

Note that the groups  $\text{Ext}_R^n(A, D)$  are also the cohomology groups of the cochain complex obtained from (7) by replacing the term  $\text{Hom}_R(A, D)$  with zero (which does not effect the cochain property), i.e., they are the cohomology groups of the cochain complex  $0 \rightarrow \text{Hom}_R(P_0, D) \rightarrow \dots$ .

We shall show below that these cohomology groups do not depend on the choice of projective resolution of  $A$ . Before doing so we identify the  $0^{\text{th}}$  cohomology group and give some examples.

**Proposition 3.** For any  $R$ -module  $A$  we have  $\text{Ext}_R^0(A, D) \cong \text{Hom}_R(A, D)$ .

*Proof:* Since the sequence  $P_1 \xrightarrow{d_1} P_0 \xrightarrow{\epsilon} A \rightarrow 0$  is exact, it follows that the corresponding sequence  $0 \rightarrow \text{Hom}_R(A, D) \xrightarrow{\epsilon} \text{Hom}_R(P_0, D) \xrightarrow{d_1} \text{Hom}_R(P_1, D)$  is also exact by Theorem 33 in Section 10.5 (noting the first comment in the proof). Hence  $\text{Ext}_R^0(A, D) = \ker d_1 = \text{image } \epsilon \cong \text{Hom}_R(A, D)$ , as claimed.

### Examples

- (1) Let  $R = \mathbb{Z}$  and let  $A = \mathbb{Z}/m\mathbb{Z}$  for some  $m \geq 2$ . By the proposition we have  $\text{Ext}_{\mathbb{Z}}^0(\mathbb{Z}/m\mathbb{Z}, D) \cong \text{Hom}_{\mathbb{Z}}(\mathbb{Z}/m\mathbb{Z}, D)$ , and it follows that  $\text{Ext}_{\mathbb{Z}}^0(\mathbb{Z}/m\mathbb{Z}, D) \cong {}_mD$ , where  ${}_mD = \{d \in D \mid md = 0\}$  are the elements of  $D$  that have order dividing  $m$ . For the higher cohomology groups, we use the simple projective resolution

$$0 \longrightarrow \mathbb{Z} \xrightarrow{m} \mathbb{Z} \longrightarrow \mathbb{Z}/m\mathbb{Z} \longrightarrow 0$$

for  $A$  given by multiplication by  $m$  on  $\mathbb{Z}$ . Taking homomorphisms into a fixed  $\mathbb{Z}$ -module  $D$  gives the cochain complex

$$0 \longrightarrow \text{Hom}_{\mathbb{Z}}(\mathbb{Z}/m\mathbb{Z}, D) \longrightarrow \text{Hom}_{\mathbb{Z}}(\mathbb{Z}, D) \xrightarrow{m} \text{Hom}_{\mathbb{Z}}(\mathbb{Z}, D) \longrightarrow 0 \longrightarrow \dots$$

We have  $D \cong \text{Hom}_{\mathbb{Z}}(\mathbb{Z}, D)$  (cf. Example 4 following Corollary 32 in Section 10.5) and under this isomorphism we have  $\text{Ext}_{\mathbb{Z}}^1(\mathbb{Z}/m\mathbb{Z}, D) \cong D/mD$  for any abelian group  $D$ . It follows immediately from the definition and the cochain complex above that  $\text{Ext}_{\mathbb{Z}}^n(\mathbb{Z}/m\mathbb{Z}, D) = 0$  for all  $n \geq 2$  and any abelian group  $D$ , which we summarize as

$$\begin{aligned}\text{Ext}_{\mathbb{Z}}^0(\mathbb{Z}/m\mathbb{Z}, D) &\cong {}_mD \\ \text{Ext}_{\mathbb{Z}}^1(\mathbb{Z}/m\mathbb{Z}, D) &\cong D/mD \\ \text{Ext}_{\mathbb{Z}}^n(\mathbb{Z}/m\mathbb{Z}, D) &= 0, \quad \text{for all } n \geq 2.\end{aligned}$$

- (2) The same abelian groups may be modules over several different rings  $R$  and the  $\text{Ext}_R$  cohomology groups depend on  $R$ . For example, suppose  $R = \mathbb{Z}/m\mathbb{Z}$  for some integer  $m \geq 1$ . An  $R$ -module  $D$  is the same as an abelian group  $D$  with exponent dividing  $m$ , i.e.,  $mD = 0$ . In particular, for any divisor  $d$  of  $m$ , the group  $\mathbb{Z}/d\mathbb{Z}$  is an  $R$ -module, and

$$\dots \xrightarrow{m/d} \mathbb{Z}/m\mathbb{Z} \xrightarrow{d} \mathbb{Z}/m\mathbb{Z} \xrightarrow{m/d} \mathbb{Z}/m\mathbb{Z} \xrightarrow{d} \mathbb{Z}/m\mathbb{Z} \longrightarrow \mathbb{Z}/d\mathbb{Z} \longrightarrow 0$$

is a projective (in fact, free) resolution of  $\mathbb{Z}/d\mathbb{Z}$  as a  $\mathbb{Z}/m\mathbb{Z}$ -module, where the final map is the natural projection mapping  $x \bmod m$  to  $x \bmod d$ . Taking homomorphisms into the  $\mathbb{Z}/m\mathbb{Z}$ -module  $D$ , using the isomorphism  $\text{Hom}_{\mathbb{Z}/m\mathbb{Z}}(\mathbb{Z}/m\mathbb{Z}, D) \cong D$ , and removing the first term gives the cochain complex

$$0 \longrightarrow D \xrightarrow{d} D \xrightarrow{m/d} D \xrightarrow{d} D \xrightarrow{m/d} \dots$$

Hence

$$\begin{aligned}\mathrm{Ext}_{\mathbb{Z}/m\mathbb{Z}}^0(\mathbb{Z}/d\mathbb{Z}, D) &\cong {}_d D, \\ \mathrm{Ext}_{\mathbb{Z}/m\mathbb{Z}}^n(\mathbb{Z}/d\mathbb{Z}, D) &\cong {}_{(m/d)} D/dD, \quad n \text{ odd, } n \geq 1, \\ \mathrm{Ext}_{\mathbb{Z}/m\mathbb{Z}}^n(\mathbb{Z}/d\mathbb{Z}, D) &\cong {}_d D/(m/d)D, \quad n \text{ even, } n \geq 2,\end{aligned}$$

where  $\kappa D = \{d \in D \mid kd = 0\}$  denotes the set of elements of  $D$  killed by  $k$ . In particular,  $\mathrm{Ext}_{\mathbb{Z}/p^2\mathbb{Z}}^n(\mathbb{Z}/p\mathbb{Z}, \mathbb{Z}/p\mathbb{Z}) \cong \mathbb{Z}/p\mathbb{Z}$  for all  $n \geq 0$ , whereas, for example,  $\mathrm{Ext}_{\mathbb{Z}}^n(\mathbb{Z}/p\mathbb{Z}, \mathbb{Z}/p\mathbb{Z}) = 0$  for all  $n \geq 2$ .

In order to show that the cohomology groups  $\mathrm{Ext}_R^n(A, D)$  are independent of the choice of projective resolution of  $A$  we shall need to be able to “compare” resolutions. The next proposition shows that an  $R$ -module homomorphism from  $A$  to  $B$  lifts to a homomorphism from a projective resolution of  $A$  to a projective resolution of  $B$  — this lifting property is one instance where the projectivity of the modules in the resolution is important.

**Proposition 4.** Let  $f : A \rightarrow A'$  be any homomorphism of  $R$ -modules and take projective resolutions of  $A$  and  $A'$ , respectively. Then for each  $n \geq 0$  there is a lift  $f_n$  of  $f$  such that the following diagram commutes:

$$\begin{array}{ccccccc} \cdots & \xrightarrow{d_2} & P_1 & \xrightarrow{d_1} & P_0 & \xrightarrow{\epsilon} & A \longrightarrow 0 \\ & & f_1 \downarrow & & f_0 \downarrow & & f \downarrow \\ \cdots & \xrightarrow{d'_2} & P'_1 & \xrightarrow{d'_1} & P'_0 & \xrightarrow{\epsilon'} & A' \longrightarrow 0 \end{array} \tag{17.8}$$

where the rows are the projective resolutions of  $A$  and  $A'$ , respectively.

*Proof:* Given the two rows and map  $f$  in (8), then since  $P_0$  is projective we may lift the map  $f\epsilon : P_0 \rightarrow A'$  to a map  $f_0 : P_0 \rightarrow P'_0$  in such a way that  $\epsilon'f_0 = f\epsilon$  (Proposition 30(2) in Section 10.5). This gives the first lift of  $f$ . Proceeding inductively in this fashion, assume  $f_n$  has been defined to make the diagram commutative to that point. Thus  $\mathrm{image} f_nd_{n+1} \subseteq \ker d'_n$ . The projectivity of  $P_{n+1}$  implies that we may lift the map  $f_nd_{n+1} : P_{n+1} \rightarrow P'_n$  to a map  $f_{n+1} : P_{n+1} \rightarrow P'_{n+1}$  to make the diagram commute at the next stage. This completes the proof.

The commutative diagram in Proposition 4 implies that the induced diagram

$$\begin{array}{ccccccc} 0 & \longrightarrow & \mathrm{Hom}_R(A, D) & \longrightarrow & \mathrm{Hom}_R(P_0, D) & \longrightarrow & \mathrm{Hom}_R(P_1, D) \longrightarrow \cdots \\ & & f \uparrow & & f_0 \uparrow & & f_1 \uparrow \\ 0 & \longrightarrow & \mathrm{Hom}_R(A, D) & \longrightarrow & \mathrm{Hom}_R(P'_0, D) & \longrightarrow & \mathrm{Hom}_R(P'_1, D) \longrightarrow \cdots \end{array} \tag{17.9}$$

is also commutative. The two rows of this diagram are cochain complexes, and this commutative diagram depicts a homomorphism of these cochain complexes. By Proposition 1 we have an induced map on their cohomology groups:

**Proposition 5.** Let  $f : A \rightarrow A'$  be a homomorphism of  $R$ -modules and take projective resolutions of  $A$  and  $A'$  as in Proposition 4. Then for every  $n$  there is an induced group homomorphism  $\varphi_n : \text{Ext}_R^n(A', D) \rightarrow \text{Ext}_R^n(A, D)$  on the cohomology groups obtained via these resolutions, and the maps  $\varphi_n$  depend only on  $f$ , not on the choice of lifts  $f_n$  in Proposition 4.

*Proof:* The existence of the map on the cohomology groups  $\text{Ext}_R^n$  follows from Proposition 1 applied to the homomorphism of cochain complexes (9). The more difficult part is showing these maps do not depend on the choice of lifts  $f_n$  in Proposition 4. This is easily seen to be equivalent to showing that if  $f$  is the zero map, then the induced maps on cohomology groups are also all zero. Assume then that  $f = 0$ . By the projectivity of the modules  $P_i$  one may inductively define  $R$ -module homomorphisms  $s_n : P_n \rightarrow P'_{n+1}$  with the property that for all  $n$ ,

$$f_n = d'_{n+1}s_n + s_{n-1}d_n \quad (17.10)$$

so the maps  $s_n$  give reverse downward diagonal arrows across the squares in (8). (The collection of maps  $\{s_n\}$  is called a *chain homotopy* between the chain homomorphism given by the  $f_n$  and the zero chain homomorphism, cf. Exercise 4.) Taking homomorphisms into  $D$  gives diagram (9) with additional upward diagonal arrows from the homomorphisms induced by the  $s_n$ , and these induced homomorphisms satisfy the relations in (10) (i.e., they form a homotopy between cochain complex homomorphisms). It is now an easy exercise using the diagonal maps added to (9) to see that any element in  $\text{Hom}_R(P'_n, D)$  representing a coset in  $\text{Ext}_R^n(A', D)$  maps to the zero coset in  $\text{Ext}_R^n(A, D)$  (cf. Exercise 4). This completes the argument.

One may also check that the homomorphism  $\varphi_0 : \text{Ext}_R^0(A', D) \rightarrow \text{Ext}_R^0(A, D)$  in Proposition 5 is the same as the map  $f : \text{Hom}_R(A', D) \rightarrow \text{Hom}_R(A, D)$  defined in Section 10.5 once the corresponding groups have been identified via the isomorphism in Proposition 3.

**Theorem 6.** The groups  $\text{Ext}_R^n(A, D)$  depend only on  $A$  and  $D$ , i.e., they are independent of the choice of projective resolution of  $A$ .

*Proof:* In the notation of Proposition 4 let  $A' = A$ , let  $f : A \rightarrow A'$  be the identity map and let the two rows of (8) be two projective resolutions of  $A$ . For any choice of lifts of the identity map, the resulting homomorphisms on cohomology groups  $\varphi_n : \text{Ext}_R^n(A', D) \rightarrow \text{Ext}_R^n(A, D)$  are seen to be isomorphisms as follows. Add a third row to the diagram (8) by copying the projective resolution in the top row below the second row. Let  $g$  be the identity map from  $A'$  to  $A$  and lift  $g$  to maps  $g_n : P'_n \rightarrow P_n$  by Proposition 4. Let  $\psi_n : \text{Ext}_R^n(A, D) \rightarrow \text{Ext}_R^n(A', D)$  be the resulting map on cohomology groups. The maps  $g_n \circ f_n : P_n \rightarrow P_n$  are now a lift of the identity map  $g \circ f$ , and they are seen to induce the homomorphisms  $\varphi_n \circ \psi_n$  on the cohomology groups. However, since the first and third rows are identical, taking the identity map from  $P_n$  to itself for all  $n$  is a particular lift of  $g \circ f$ , and this choice clearly induces the identity map on cohomology groups. The last assertion of Proposition 5 then implies that  $\varphi_n \circ \psi_n$  is also the identity on  $\text{Ext}_R^n(A, D)$ . By a symmetric argument  $\psi_n \circ \varphi_n$  is the

identity on  $\text{Ext}_R^n(A', D)$ . This shows the maps  $\varphi_n$  and  $\psi_n$  are isomorphisms, as needed to complete the proof.

For a fixed  $R$ -module  $D$  and fixed integer  $n \geq 0$ , Proposition 5 and Theorem 6 show that  $\text{Ext}_R^n(\_, D)$  defines a (contravariant) functor from the category of  $R$ -modules to the category of abelian groups.

The next result shows that projective resolutions for a submodule and corresponding quotient module of an  $R$ -module  $M$  can be fit together to give a projective resolution of  $M$ .

**Proposition 7. (Simultaneous Resolution)** Let  $0 \rightarrow L \rightarrow M \rightarrow N \rightarrow 0$  be a short exact sequence of  $R$ -modules, let  $L = A$  have a projective resolution as in (6) above, and let  $N$  have a similar projective resolution where the projective modules are denoted by  $\overline{P}_n$ . Then there is a resolution of  $M$  by the projective modules  $P_n \oplus \overline{P}_n$  such that the following diagram commutes:

$$\begin{array}{ccccccc}
& \vdots & & \vdots & & \vdots & \\
& \downarrow & & \downarrow & & \downarrow & \\
0 & \longrightarrow & P_1 & \longrightarrow & P_1 \oplus \overline{P}_1 & \longrightarrow & \overline{P}_1 \longrightarrow 0 \\
& \downarrow & & \downarrow & & \downarrow & \\
0 & \longrightarrow & P_0 & \longrightarrow & P_0 \oplus \overline{P}_0 & \longrightarrow & \overline{P}_0 \longrightarrow 0 & (17.11) \\
& \downarrow & & \downarrow & & \downarrow & \\
0 & \longrightarrow & L & \longrightarrow & M & \longrightarrow & N \longrightarrow 0 \\
& \downarrow & & \downarrow & & \downarrow & \\
0 & & 0 & & 0 & & 0
\end{array}$$

Moreover, the rows and columns of this diagram are exact and the rows are split.

*Proof:* The left and right nonzero columns of (11) are exact by hypothesis. The modules in the middle column are projective (cf. Exercise 3, Section 10.5) and the row maps are the obvious ones to make each row a split exact sequence. It remains then to define the vertical maps in the middle column in such a way as to make the diagram commute. This is accomplished in a straightforward manner, working inductively from the bottom upward — the first step in this process is outlined in Exercise 5.

Theorem 2 and Proposition 7 now yield the long exact sequence for  $\text{Ext}_R$  that extends the exact sequence (2).

**Theorem 8.** Let  $0 \rightarrow L \rightarrow M \rightarrow N \rightarrow 0$  be a short exact sequence of  $R$ -modules. Then there is a long exact sequence of abelian groups

$$\begin{aligned} 0 \rightarrow \text{Hom}_R(N, D) &\rightarrow \text{Hom}_R(M, D) \rightarrow \text{Hom}_R(L, D) \xrightarrow{\delta_0} \text{Ext}_R^1(N, D) \\ &\rightarrow \text{Ext}_R^1(M, D) \rightarrow \text{Ext}_R^1(L, D) \xrightarrow{\delta_1} \text{Ext}_R^2(N, D) \rightarrow \dots \end{aligned} \quad (17.12)$$

where the maps between groups at the same level  $n$  are as in Proposition 5 and the connecting homomorphisms  $\delta_n$  are given by Theorem 2.

*Proof:* Take a simultaneous projective resolution of the short exact sequence as in Proposition 7 and take homomorphisms into  $D$ . To obtain the cohomology groups  $\text{Ext}_R^n$  from the resulting diagram, as noted in the discussion preceding Proposition 3 we replace the lowest nonzero row in the transformed diagram with a row of zeros to get the following commutative diagram:

$$\begin{array}{ccccccc} & \vdots & & \vdots & & \vdots & \\ & \uparrow & & \uparrow & & \uparrow & \\ 0 & \longrightarrow & \text{Hom}_R(\bar{P}_1, D) & \longrightarrow & \text{Hom}_R(P_1 \oplus \bar{P}_1, D) & \longrightarrow & \text{Hom}_R(P_1, D) \longrightarrow 0 \\ & \uparrow & & \uparrow & & \uparrow & \\ 0 & \longrightarrow & \text{Hom}_R(\bar{P}_0, D) & \longrightarrow & \text{Hom}_R(P_0 \oplus \bar{P}_0, D) & \longrightarrow & \text{Hom}_R(P_0, D) \longrightarrow 0 \\ & \uparrow & & \uparrow & & \uparrow & \\ & 0 & & 0 & & 0 & \end{array} \quad (17.13)$$

The columns of (13) are cochain complexes, and the rows are split by Proposition 29(2) of Section 10.5 and the discussion following it. Thus (13) is a short exact sequence of cochain complexes. Theorem 2 then gives a long exact sequence of cohomology groups whose terms are, by definition, the groups  $\text{Ext}_R^n(\_, D)$ , for  $n \geq 0$ . The 0<sup>th</sup> order terms are identified by Proposition 3, completing the proof.

Theorem 8 shows how the exact sequence (2) can be extended in a natural way and shows that the group  $\text{Ext}_R^1(N, D)$  is the first measure of the failure of (2) to be exact on the right — in fact (2) can be extended to a short exact sequence on the right if and only if the connecting homomorphism  $\delta_0$  in (12) is the zero homomorphism. In particular, if  $\text{Ext}_R^1(N, D) = 0$  for all  $R$ -modules  $N$ , then (2) will be exact on the right for *every* exact sequence (1). We have already seen (Corollary 35 in Section 10.5) that this implies the  $R$ -module  $D$  is injective. Part of the next result shows that the converse is also true and characterizes injective modules in terms of  $\text{Ext}_R$  groups.

**Proposition 9.** For an  $R$ -module  $Q$  the following are equivalent:

- (1)  $Q$  is injective,
- (2)  $\text{Ext}_R^1(A, Q) = 0$  for all  $R$ -modules  $A$ , and
- (3)  $\text{Ext}_R^n(A, Q) = 0$  for all  $R$ -modules  $A$  and all  $n \geq 1$ .

*Proof:* We showed (2) implies (1) above, and (3) implies (2) is trivial, so it remains to show that if  $Q$  is injective then  $\text{Ext}_R^n(A, Q) = 0$  for all  $R$ -modules  $A$  and all  $n \geq 1$ . Take a projective resolution

$$\cdots \rightarrow P_n \rightarrow P_{n-1} \rightarrow \cdots \rightarrow P_0 \rightarrow A \rightarrow 0$$

for  $A$ . Since  $Q$  is injective, the sequence

$$0 \rightarrow \text{Hom}_R(A, Q) \rightarrow \text{Hom}_R(P_0, Q) \rightarrow \cdots \rightarrow \text{Hom}_R(P_{n-1}, Q) \rightarrow \text{Hom}_R(P_n, Q) \rightarrow \cdots$$

is still exact (Corollary 35 in Section 10.5), so all of the cohomology groups for this cochain complex are 0. In particular, the groups  $\text{Ext}_R^n(A, Q)$  for  $n \geq 1$  are all trivial, which is (3).

For a fixed  $R$ -module  $D$ , the result in Theorem 8 can be viewed as explaining what happens to the short exact sequence  $0 \rightarrow L \rightarrow M \rightarrow N \rightarrow 0$  on the right after applying the left exact functor  $\text{Hom}_R(\_, D)$ . This is why the (contravariant) functors  $\text{Ext}_R^*(\_, D)$  are called the *right derived functors* for the functor  $\text{Hom}_R(\_, D)$ .

One can also consider the effect of applying the left exact functor  $\text{Hom}_R(D, \_)$ , i.e., by taking homomorphisms *from*  $D$  rather than *into*  $D$ . The next theorem shows that in fact the same  $\text{Ext}_R$  groups define the (covariant) right derived functors for  $\text{Hom}_R(D, \_)$  as well.

**Theorem 10.** Let  $0 \rightarrow L \rightarrow M \rightarrow N \rightarrow 0$  be a short exact sequence of  $R$ -modules. Then there is a long exact sequence of abelian groups

$$\begin{aligned} 0 \rightarrow \text{Hom}_R(D, L) &\rightarrow \text{Hom}_R(D, M) \rightarrow \text{Hom}_R(D, N) \xrightarrow{\gamma_0} \text{Ext}_R^1(D, L) \\ &\rightarrow \text{Ext}_R^1(D, M) \rightarrow \text{Ext}_R^1(D, N) \xrightarrow{\gamma_1} \text{Ext}_R^2(D, L) \rightarrow \cdots \end{aligned} \tag{17.14}$$

*Proof:* Let  $0 \rightarrow L \rightarrow M \rightarrow N \rightarrow 0$  be a short exact sequence of  $R$ -modules. By taking a projective resolution of  $D$  and then applying  $\text{Hom}_R(\_, L)$ ,  $\text{Hom}_R(\_, M)$  and  $\text{Hom}_R(\_, N)$  to this resolution one obtains the columns in a commutative diagram similar to (13), but with  $L$ ,  $M$  and  $N$  in the second positions rather than the first. Applying the Long Exact Sequence Theorem to this array gives (14).

Theorem 10 shows that the group  $\text{Ext}_R^1(D, L)$  measures whether the exact sequence

$$0 \rightarrow \text{Hom}_R(D, L) \rightarrow \text{Hom}_R(D, M) \rightarrow \text{Hom}_R(D, N)$$

can be extended to a short exact sequence — it can be extended if and only if  $\gamma_0$  is the zero homomorphism. In particular, this will always be the case if the module  $D$  has the property that  $\text{Ext}_R^1(D, B) = 0$  for all  $R$ -modules  $B$ ; in this case it follows by Corollary 32 in Section 10.5 that  $D$  is a projective  $R$ -module. As in the situation of injective  $R$ -modules in Proposition 9, the vanishing of these cohomology groups in fact characterizes projective  $R$ -modules:

**Proposition 11.** For an  $R$ -module  $P$  the following are equivalent:

- (1)  $P$  is projective,
- (2)  $\text{Ext}_R^1(P, B) = 0$  for all  $R$ -modules  $B$ , and
- (3)  $\text{Ext}_R^n(P, B) = 0$  for all  $R$ -modules  $B$  and all  $n \geq 1$ .

*Proof.* We proved (2) implies (1) above, and (3) implies (2) is trivial, so it remains to prove that (1) implies (3). If  $P$  is a projective  $R$ -module, then the simple exact sequence

$$0 \longrightarrow P \xrightarrow{1} P \longrightarrow 0$$

given by the identity map on  $P$  is a projective resolution of  $P$ . Taking homomorphisms into  $B$  gives the simple cochain complex

$$0 \rightarrow \text{Hom}_R(P, B) \xrightarrow{1} \text{Hom}_R(P, B) \rightarrow 0 \rightarrow \cdots \rightarrow 0 \rightarrow \cdots$$

from which it follows by definition that  $\text{Ext}_R^n(P, B) = 0$  for all  $n \geq 1$ , which gives (3).

### Examples

- (1) Since  $\mathbb{Z}^m$  is a free, hence projective,  $\mathbb{Z}$ -module, it follows from Proposition 11 that

$$\text{Ext}_{\mathbb{Z}}^n(\mathbb{Z}^m, B) = 0$$

for all abelian groups  $B$ , all  $m \geq 1$ , and all  $n \geq 1$ .

- (2) It is not difficult to show that  $\text{Ext}_R^n(A_1 \oplus A_2, B) \cong \text{Ext}_R^n(A_1, B) \oplus \text{Ext}_R^n(A_2, B)$  for all  $n \geq 0$  (cf. Exercise 10), so the previous example together with the example following Proposition 3 determines  $\text{Ext}_{\mathbb{Z}}^n(A, B)$  for all finitely generated abelian groups  $A$ . In particular,  $\text{Ext}_{\mathbb{Z}}^n(A, B) = 0$  for all finitely generated groups  $A$ , all abelian groups  $B$ , and all  $n \geq 2$ .

We have chosen to define the cohomology group  $\text{Ext}_R^n(A, B)$  using a projective resolution of  $A$ . There is a parallel development using an *injective resolution* of  $B$ :

$$0 \rightarrow B \rightarrow Q_0 \rightarrow Q_1 \rightarrow \cdots$$

where each  $Q_i$  is injective. In this situation one defines  $\text{Ext}_R^n(A, B)$  as the  $n^{\text{th}}$  cohomology group of the cochain sequence obtained by applying  $\text{Hom}_R(A, \underline{\quad})$  to the resolution for  $B$ . The theory proceeds in a manner analogous to the development of this section. Ultimately one shows that there is a natural isomorphism between the groups  $\text{Ext}_R^n(A, B)$  constructed using both methods.

### Examples

- (1) Suppose  $R = \mathbb{Z}$  and  $A$  and  $B$  are  $\mathbb{Z}$ -modules, i.e., are abelian groups. Recall that a  $\mathbb{Z}$ -module is injective if and only if it is divisible (Proposition 36 in Section 10.5). The group  $B$  can be embedded in an injective  $\mathbb{Z}$ -module  $Q_0$  (Corollary 37 in Section 10.5) and the quotient,  $Q_1$ , of  $Q_0$  by the image of  $B$  is again injective. Hence we have an injective resolution

$$0 \longrightarrow B \longrightarrow Q_0 \longrightarrow Q_1 \longrightarrow 0$$

of  $B$ . Applying  $\text{Hom}_{\mathbb{Z}}(A, \underline{\quad})$  to this sequence gives the cochain complex

$$0 \longrightarrow \text{Hom}_{\mathbb{Z}}(A, B) \longrightarrow \text{Hom}_{\mathbb{Z}}(A, \mathbb{Q}_0) \longrightarrow \text{Hom}_{\mathbb{Z}}(A, \mathbb{Q}_1) \longrightarrow 0 \longrightarrow \dots$$

from which it follows immediately that

$$\text{Ext}_{\mathbb{Z}}^n(A, B) = 0$$

for all abelian groups  $A$  and  $B$  and all  $n \geq 2$ , showing that the result of the previous example holds also when  $A$  is not finitely generated.

- (2) Suppose  $A$  is a torsion abelian group. Then we have  $\text{Ext}^0(A, \mathbb{Z}) \cong \text{Hom}(A, \mathbb{Z}) = 0$  since  $\mathbb{Z}$  is torsion free. The sequence  $0 \rightarrow \mathbb{Z} \rightarrow \mathbb{Q} \rightarrow \mathbb{Q}/\mathbb{Z} \rightarrow 0$  gives an injective resolution of  $\mathbb{Z}$ . Applying  $\text{Hom}(A, \underline{\quad})$  gives the cochain complex

$$0 \longrightarrow \text{Hom}(A, \mathbb{Z}) \longrightarrow \text{Hom}(A, \mathbb{Q}) \longrightarrow \text{Hom}(A, \mathbb{Q}/\mathbb{Z}) \longrightarrow 0 \longrightarrow \dots$$

and since  $\mathbb{Q}$  is also torsion free, this shows that

$$\text{Ext}_{\mathbb{Z}}^1(A, \mathbb{Z}) \cong \text{Hom}_{\mathbb{Z}}(A, \mathbb{Q}/\mathbb{Z}).$$

The group  $\text{Hom}(A, \mathbb{Q}/\mathbb{Z})$  is called the *Pontriagin dual group* to  $A$ . If  $A$  is a finite abelian group the Pontriagin dual of  $A$  is isomorphic to  $A$  (cf. Exercise 14, Section 5.2). In particular,  $\text{Ext}^1(A, \mathbb{Z}) \cong A$  is nonzero for all nonzero finite abelian groups  $A$ . We have  $\text{Ext}^n(A, \mathbb{Z}) = 0$  for all  $n \geq 2$  by the previous example.

We record an important property of  $\text{Ext}_R^1$ , which helps to explain the name for these cohomology groups. Recall that equivalent extensions were defined at the beginning of Section 10.5.

**Theorem 12.** For any  $R$ -modules  $N$  and  $L$  there is a bijection between  $\text{Ext}_R^1(N, L)$  and the set of equivalence classes of extensions of  $N$  by  $L$ .

Although we shall not prove this result, in Section 4 we establish a similar bijection between equivalence classes of group extensions of  $G$  by  $A$  and elements of a certain cohomology group, where  $G$  is any finite group and  $A$  is any  $\mathbb{Z}G$ -module.

### Example

Suppose  $R = \mathbb{Z}$  and  $A = B = \mathbb{Z}/p\mathbb{Z}$ . We showed above that  $\text{Ext}_R^1(\mathbb{Z}/p\mathbb{Z}, \mathbb{Z}/p\mathbb{Z}) \cong \mathbb{Z}/p\mathbb{Z}$ , so by Theorem 12 there are precisely  $p$  equivalence classes of extensions of  $\mathbb{Z}/p\mathbb{Z}$  by  $\mathbb{Z}/p\mathbb{Z}$ . These are given by the direct sum  $\mathbb{Z}/p\mathbb{Z} \oplus \mathbb{Z}/p\mathbb{Z}$  (which corresponds to the trivial class in  $\text{Ext}_R^1(\mathbb{Z}/p\mathbb{Z}, \mathbb{Z}/p\mathbb{Z})$ ) and the  $p - 1$  extensions

$$0 \longrightarrow \mathbb{Z}/p\mathbb{Z} \longrightarrow \mathbb{Z}/p^2\mathbb{Z} \xrightarrow{i} \mathbb{Z}/p\mathbb{Z} \longrightarrow 0$$

defined by the map  $i(x) = ix \bmod p$  for  $i = 1, 2, \dots, p - 1$ . Note that while these are inequivalent as extensions, they all determine the same group  $\mathbb{Z}/p^2\mathbb{Z}$ .

## Tensor Products and the Groups $\text{Tor}_n^R(A, B)$

The cohomology groups  $\text{Ext}_R^n(A, B)$  determine what happens to short exact sequences on the right after applying the left exact functors  $\text{Hom}_R(D, \underline{\phantom{x}})$  and  $\text{Hom}_R(\underline{\phantom{x}}, D)$ . One may similarly ask for the behavior of short exact sequences on the left after applying the right exact functor  $D \otimes_R \underline{\phantom{x}}$  or the right exact functor  $\underline{\phantom{x}} \otimes_R D$ . This leads to the Tor (homology) groups (whose name derives from their relation to torsion submodules), and we now briefly outline the development of these left derived functors. In some respects this theory is “dual” to the theory for  $\text{Ext}_R$ . We concentrate on the situation for  $D \otimes_R \underline{\phantom{x}}$  when  $D$  is a right  $R$ -module. When  $D$  is a left  $R$ -module there is a completely symmetric theory for  $\underline{\phantom{x}} \otimes_R D$ ; when  $R$  is commutative and all  $R$ -modules have the same left and right  $R$  action the homology groups resulting from both developments are isomorphic.

Suppose then that  $D$  is a right  $R$ -module. Then for every left  $R$ -module  $B$  the tensor product  $D \otimes_R B$  is an abelian group and the functor  $D \otimes \underline{\phantom{x}}$  is covariant and right exact, i.e., for any short exact sequence (1) of left  $R$ -modules,

$$D \otimes L \longrightarrow D \otimes M \longrightarrow D \otimes N \longrightarrow 0$$

is an exact sequence of abelian groups. This sequence may be extended at the left end to a long exact sequence as follows. Let

$$\cdots \longrightarrow P_n \xrightarrow{d_n} P_{n-1} \longrightarrow \cdots \xrightarrow{d_1} P_0 \xrightarrow{\epsilon} B \longrightarrow 0$$

be a projective resolution of  $B$ , and take tensor products with  $D$  to obtain

$$\cdots \longrightarrow D \otimes P_n \xrightarrow{1 \otimes d_n} D \otimes P_{n-1} \longrightarrow \cdots \xrightarrow{1 \otimes d_1} D \otimes P_0 \xrightarrow{1 \otimes \epsilon} D \otimes B \longrightarrow 0. \quad (17.15)$$

It follows from the argument in Theorem 39 of Section 10.5 that (15) is a chain complex — the composition of any two successive maps is zero — so we may form its homology groups.

**Definition.** Let  $D$  be a right  $R$ -module and let  $B$  be a left  $R$ -module. For any projective resolution of  $B$  by left  $R$ -modules as above let  $1 \otimes d_n : D \otimes P_n \rightarrow D \otimes P_{n-1}$  for all  $n \geq 1$  as in (15). Then

$$\text{Tor}_n^R(D, B) = \ker(1 \otimes d_n) / \text{image}(1 \otimes d_{n+1})$$

where  $\text{Tor}_0^R(D, B) = (D \otimes P_0) / \text{image}(1 \otimes d_1)$ . The group  $\text{Tor}_n^R(D, B)$  is called the  $n^{\text{th}}$  homology group derived from the functor  $D \otimes \underline{\phantom{x}}$ . When  $R = \mathbb{Z}$  the group  $\text{Tor}_n^{\mathbb{Z}}(D, B)$  is also denoted simply  $\text{Tor}_n(D, B)$ .

Thus  $\text{Tor}_n^R(D, B)$  is the  $n^{\text{th}}$  homology group of the chain complex obtained from (15) by removing the term  $D \otimes B$ .

A completely analogous proof to Proposition 3 (but relying on Theorem 39 in Section 10.5) implies the following:

**Proposition 13.** For any left  $R$ -module  $B$  we have  $\text{Tor}_0^R(D, B) \cong D \otimes B$ .

### Example

Let  $R = \mathbb{Z}$  and let  $B = \mathbb{Z}/m\mathbb{Z}$  for some  $m \geq 2$ . By the proposition,  $\text{Tor}_0^{\mathbb{Z}}(D, \mathbb{Z}/m\mathbb{Z})$  is isomorphic to  $D \otimes \mathbb{Z}/m\mathbb{Z}$ , so we have  $\text{Tor}_0^{\mathbb{Z}}(D, \mathbb{Z}/m\mathbb{Z}) \cong D/mD$  (Example 8 following Corollary 12 in Section 10.4). For the higher groups we apply  $D \otimes \underline{\phantom{x}}$  to the projective resolution

$$0 \longrightarrow \mathbb{Z} \xrightarrow{m} \mathbb{Z} \longrightarrow \mathbb{Z}/m\mathbb{Z} \longrightarrow 0$$

of  $B$  and use the isomorphisms  $D \otimes \mathbb{Z} \cong D$  and  $D \otimes \mathbb{Z}/m\mathbb{Z} \cong D/mD$ . This gives the chain complex

$$\dots \longrightarrow 0 \longrightarrow D \xrightarrow{m} D \longrightarrow D/mD \longrightarrow 0.$$

It follows that  $\text{Tor}_1^{\mathbb{Z}}(D, \mathbb{Z}/m\mathbb{Z}) \cong {}_mD$  is the subgroup of  $D$  annihilated by  $m$  and that  $\text{Tor}_n^{\mathbb{Z}}(D, \mathbb{Z}/m\mathbb{Z}) = 0$  for all  $n \geq 2$ , which we summarize as

$$\begin{aligned}\text{Tor}_0(D, \mathbb{Z}/m\mathbb{Z}) &\cong D/mD, \\ \text{Tor}_1(D, \mathbb{Z}/m\mathbb{Z}) &\cong {}_mD, \\ \text{Tor}_n(D, \mathbb{Z}/m\mathbb{Z}) &= 0, \quad \text{for all } n \geq 2.\end{aligned}$$

As for  $\text{Ext}$ , the  $\text{Tor}$  groups depend on the ring  $R$  (cf. Exercise 20).

Following a similar development to that for  $\text{Ext}_R$ , one shows:

### Proposition 14.

- (1) The homology groups  $\text{Tor}_n^R(D, B)$  are independent of the choice of projective resolution of  $B$ , and
- (2) for every  $R$ -module homomorphism  $f : B \rightarrow B'$  there are induced maps  $\psi_n : \text{Tor}_n^R(D, B) \rightarrow \text{Tor}_n^R(D, B')$  on homology groups (depending only on  $f$ ).

There is a Long Exact Sequence in Homology analogous to Theorem 2, except that all the arrows are reversed, whose proof follows mutatis mutandis from the argument for cohomology. This together with Simultaneous Resolution gives:

**Theorem 15.** Let  $0 \rightarrow L \rightarrow M \rightarrow N \rightarrow 0$  be a short exact sequence of left  $R$ -modules. Then there is a long exact sequence of abelian groups

$$\begin{aligned}\dots &\rightarrow \text{Tor}_2^R(D, N) \xrightarrow{\delta_1} \text{Tor}_1^R(D, L) \rightarrow \text{Tor}_1^R(D, M) \rightarrow \\ &\text{Tor}_1^R(D, N) \xrightarrow{\delta_0} D \otimes L \rightarrow D \otimes M \rightarrow D \otimes N \rightarrow 0\end{aligned}$$

where the maps between groups at the same level  $n$  are as in Proposition 14 (and the maps  $\delta_n$  are called connecting homomorphisms).

There is a characterization of flat modules corresponding to Propositions 9 and 11 whose proof is very similar and is left as an exercise.

**Proposition 16.** For a right  $R$ -module  $D$  the following are equivalent:

- (1)  $D$  is a flat  $R$ -module,
- (2)  $\text{Tor}_1^R(D, B) = 0$  for all left  $R$ -modules  $B$ , and
- (3)  $\text{Tor}_n^R(D, B) = 0$  for all left  $R$ -modules  $B$  and all  $n \geq 1$ .

We have defined  $\text{Tor}_n^R(A, B)$  as the homology of the chain complex obtained by tensoring a projective resolution of  $B$  on the left with  $A$ . The same groups are obtained by taking the homology of the chain complex obtained by tensoring a projective resolution of  $A$  on the right by  $B$ . Put another way, the  $\text{Tor}_n^R(A, B)$  groups define the (covariant) left derived functors for both of the right exact functors  $A \otimes_R \underline{\quad}$  and  $\underline{\quad} \otimes_R B$ : if  $D$  is a left  $R$ -module, then the short exact sequence  $0 \rightarrow L \rightarrow M \rightarrow N \rightarrow 0$  of right  $R$ -modules gives rise to the long exact sequence

$$\cdots \rightarrow \text{Tor}_2^R(N, D) \xrightarrow{\gamma_1} \text{Tor}_1^R(L, D) \rightarrow \text{Tor}_1^R(M, D) \rightarrow \\ \text{Tor}_1^R(N, D) \xrightarrow{\gamma_0} L \otimes_R D \rightarrow M \otimes_R D \rightarrow N \otimes_R D \rightarrow 0$$

of abelian groups. In particular, the left  $R$ -module  $D$  is flat if and only if  $\text{Tor}_1^R(A, D) = 0$  for all right  $R$ -modules  $A$ .

When  $R$  is commutative,  $A \otimes_R B \cong B \otimes_R A$  (Proposition 20 in Section 10.4) for any two  $R$ -modules  $A$  and  $B$  with the standard  $R$ -module structures, and it follows that  $\text{Tor}_n^R(A, B) \cong \text{Tor}_n^R(B, A)$  as  $R$ -modules. When  $R$  is commutative the Tor long exact sequences are exact sequences of  $R$ -modules.

## Examples

- (1) If  $R = \mathbb{Z}$ , then since  $\mathbb{Z}^m$  is free, hence flat (Corollary 42, Section 10.5), we have  $\text{Tor}_n(\mathbb{A}, \mathbb{Z}^m) = 0$  for all  $n \geq 1$  and all abelian groups  $A$ .
- (2) Since  $\text{Tor}_n^R(A, B_1 \oplus B_2) \cong \text{Tor}_n^R(A, B_1) \oplus \text{Tor}_n^R(A, B_2)$  (cf. Exercise 10), the previous two examples together determine  $\text{Tor}_n^R(A, B)$  for all abelian groups  $A$  and all finitely generated abelian groups  $B$ .
- (3) As a particular case of the previous example,  $\text{Tor}_1(A, B)$  is a torsion group and  $\text{Tor}_n(A, B) = 0$  for every abelian group  $A$ , every finitely generated abelian group  $B$ , and all  $n \geq 2$ . In fact these results hold without the condition that  $B$  be finitely generated.
- (4) The exact sequence  $0 \rightarrow \mathbb{Z} \rightarrow \mathbb{Q} \rightarrow \mathbb{Q}/\mathbb{Z} \rightarrow 0$  gives the long exact sequence

$$\cdots \rightarrow \text{Tor}_1(D, \mathbb{Q}) \rightarrow \text{Tor}_1(D, \mathbb{Q}/\mathbb{Z}) \rightarrow D \otimes \mathbb{Z} \rightarrow D \otimes \mathbb{Q} \rightarrow D \otimes \mathbb{Q}/\mathbb{Z} \rightarrow 0.$$

Since  $\mathbb{Q}$  is a flat  $\mathbb{Z}$ -module (Example 2 following Corollary 42 in Section 10.5), the proposition shows that we have an exact sequence

$$0 \longrightarrow \text{Tor}_1(D, \mathbb{Q}/\mathbb{Z}) \longrightarrow D \longrightarrow D \otimes \mathbb{Q}$$

and so  $\text{Tor}_1(D, \mathbb{Q}/\mathbb{Z})$  is isomorphic to the kernel of the natural map from  $D$  into  $D \otimes \mathbb{Q}$ , which is the torsion subgroup of  $D$  (cf. Exercise 9 in Section 10.4).

The following results show that, for  $R = \mathbb{Z}$ , the Tor groups are closely related to torsion subgroups. The Tor groups first arose in applications of torsion abelian groups in topological settings, which helps explain the terminology.

**Proposition 17.** Let  $A$  and  $B$  be  $\mathbb{Z}$ -modules and let  $t(A)$  and  $t(B)$  denote their respective torsion submodules. Then  $\text{Tor}_1(A, B) \cong \text{Tor}_1(t(A), t(B))$ .

*Proof:* In the case where  $A$  and  $B$  are finitely generated abelian groups this follows by Examples 3 and 4 above. For the general case, cf. Exercise 16.

**Corollary 18.** If  $A$  is an abelian group then  $A$  is torsion free if and only if  $\text{Tor}_1(A, B) = 0$  for every abelian group  $B$  (in which case  $A$  is flat as a  $\mathbb{Z}$ -module).

*Proof:* By the proposition, if  $A$  has no elements of finite order then we have  $\text{Tor}_1(A, B) = \text{Tor}_1(t(A), B) = \text{Tor}_1(0, B) = 0$  for every abelian group  $B$ . Conversely, if  $\text{Tor}_1(A, B) = 0$  for all  $B$ , then in particular  $\text{Tor}_1(A, \mathbb{Q}/\mathbb{Z}) = 0$ , and this group is isomorphic to the torsion subgroup of  $A$  by the example above.

The results of Proposition 17 and Corollary 18 hold for any P.I.D.  $R$  in place of  $\mathbb{Z}$  (cf. Exercise 26 in Section 10.5 and Exercise 16).

Finally, we mention that the cohomology and homology theories we have described may be developed in a vastly more general setting by axiomatizing the essential properties of  $R$ -modules and the  $\text{Hom}_R$  and tensor product functors. This leads to the general notions of *abelian categories* and *additive functors*. In the case of the abelian category of  $R$ -modules, any additive functor  $\mathcal{F}$  to the category of abelian groups gives rise to a set of *derived functors*,  $\mathcal{F}_n$ , also from  $R$ -modules to abelian groups, for all  $n \geq 0$ . Then for each short exact sequence  $0 \rightarrow L \rightarrow M \rightarrow N \rightarrow 0$  of  $R$ -modules there is a long exact sequence of (cohomology or homology) groups whose terms are  $\mathcal{F}_n(L)$ ,  $\mathcal{F}_n(M)$  and  $\mathcal{F}_n(N)$ , and these long exact sequences reflect the exactness properties of the functor  $\mathcal{F}$ . If  $\mathcal{F}$  is left or right exact then the  $0^{\text{th}}$  derived functor  $\mathcal{F}_0$  is naturally equivalent to  $\mathcal{F}$  (hence the  $0^{\text{th}}$  degree groups  $\mathcal{F}_0(X)$  are isomorphic to  $\mathcal{F}(X)$ ), and if  $\mathcal{F}$  is an exact functor then  $\mathcal{F}_n(X) = 0$  for all  $n \geq 1$  and all  $R$ -modules  $X$ .

## EXERCISES

1. Give the details of the proof of Proposition 1.
2. This exercise defines the connecting map  $\delta_n$  in the Long Exact Sequence of Theorem 2 and proves it is a homomorphism. In the notation of Theorem 2 let  $0 \rightarrow \mathcal{A} \xrightarrow{\alpha} \mathcal{B} \xrightarrow{\beta} \mathcal{C} \rightarrow 0$  be a short exact sequence of cochain complexes, where for simplicity the cochain maps for  $\mathcal{A}$ ,  $\mathcal{B}$  and  $\mathcal{C}$  are all denoted by the same  $d$ .
  - (a) If  $c \in C^n$  represents the class  $x \in H^n(\mathcal{C})$  show that there is some  $b \in B^n$  with  $\beta_n(b) = c$ .
  - (b) Show that  $d_{n+1}(b) \in \ker \beta_{n+1}$  and conclude that there is a unique  $a \in A^{n+1}$  such that  $\alpha_{n+1}(a) = d_{n+1}(b)$ . [Use  $c \in \ker d_{n+1}$  and the commutativity of the diagram.]
  - (c) Show that  $d_{n+2}(a) = 0$  and conclude that  $a$  defines a class  $\bar{a}$  in the quotient group  $H^{n+1}(\mathcal{A})$ . [Use the fact that  $\alpha_{n+2}$  is injective.]
  - (d) Prove that  $\bar{a}$  is independent of the choice of  $b$ , i.e., if  $b'$  is another choice and  $a'$  is its unique preimage in  $A^{n+1}$  then  $\bar{a} = \bar{a}'$ , and that  $\bar{a}$  is also independent of the choice of  $c$  representing the class  $x$ .
  - (e) Define  $\delta_n(x) = \bar{a}$  and prove that  $\delta_n$  is a group homomorphism from  $H^n(\mathcal{C})$  to  $H^{n+1}(\mathcal{A})$ . [Use the fact that  $\delta_n(x)$  is independent of the choices of  $c$  and  $b$  to compute  $\delta_n(x_1 + x_2)$ .]

3. Suppose

$$\begin{array}{ccccccc} & A & \xrightarrow{\alpha} & B & \xrightarrow{\beta} & C & \longrightarrow 0 \\ f \downarrow & & g \downarrow & & h \downarrow & & \\ 0 & \longrightarrow & A' & \xrightarrow{\alpha'} & B' & \xrightarrow{\beta'} & C' \end{array}$$

is a commutative diagram of  $R$ -modules with exact rows.

- (a) If  $c \in \ker h$  and  $\beta(b) = c$  prove that  $g(b) \in \ker \beta'$  and conclude that  $g(b) = \alpha'(a')$  for some  $a' \in A'$ . [Use the commutativity of the diagram.]
- (b) Show that  $\delta(c) = a' \bmod \text{image } f$  is a well defined  $R$ -module homomorphism from  $\ker h$  to the quotient  $A'/\text{image } f$ .
- (c) (*The Snake Lemma*) Prove there is an exact sequence

$$\ker f \longrightarrow \ker g \longrightarrow \ker h \xrightarrow{\delta} \text{coker } f \longrightarrow \text{coker } g \longrightarrow \text{coker } h$$

where  $\text{coker } f$  (the *cokernel* of  $f$ ) is  $A'/(\text{image } f)$  and similarly for  $\text{coker } g$  and  $\text{coker } h$ .

- (d) Show that if  $\alpha$  is injective and  $\beta'$  is surjective (i.e., the two rows in the commutative diagram above can be extended to short exact sequences) then the exact sequence in (c) can be extended to the exact sequence

$$0 \longrightarrow \ker f \longrightarrow \ker g \longrightarrow \ker h \xrightarrow{\delta} \text{coker } f \longrightarrow \text{coker } g \longrightarrow \text{coker } h \longrightarrow 0$$

4. Let  $\mathcal{A} = \{A^n\}$  and  $\mathcal{B} = \{B^n\}$  be cochain complexes, where the maps  $A^n \rightarrow A^{n+1}$  and  $B^n \rightarrow B^{n+1}$  in both complexes are denoted by  $d_{n+1}$  for all  $n$ . Cochain complex homomorphisms  $\alpha$  and  $\beta$  from  $\mathcal{A}$  to  $\mathcal{B}$  are said to be *homotopic* if for all  $n$  there are module homomorphisms  $s_n : A^{n+1} \rightarrow B^n$  such that the maps  $\alpha_n - \beta_n$  from  $A^n$  to  $B^n$  satisfy

$$\alpha_n - \beta_n = d_n s_{n-1} + s_n d_{n+1}.$$

The collection of maps  $\{s_n\}$  is called a *cochain homotopy* from  $\alpha$  to  $\beta$ . One may similarly define chain homotopies between chain complexes.

- (a) Prove that homotopic maps of cochain complexes induce the same maps on cohomology, i.e., if  $\alpha$  and  $\beta$  are homotopic homomorphisms of cochain complexes then the induced group homomorphisms from  $H^n(\mathcal{A})$  to  $H^n(\mathcal{B})$  are equal for every  $n \geq 0$ . (Thus “homotopy” gives a sufficient condition for two maps of complexes to induce the same maps on cohomology or homology; this condition is not in general necessary.) [Use the definition of homotopy to show  $(\alpha_n - \beta_n)(z) \in \text{image } d_n$  for every  $z \in \ker d_{n+1}$ .]
- (b) Prove that the relation  $\alpha \sim \beta$  if  $\alpha$  and  $\beta$  are homotopic is an equivalence relation on any set of cochain complex homomorphisms.

5. Establish the first step in the Simultaneous Resolution result of Proposition 7 as follows: assume the first two nonzero rows in diagram (11) are given, except for the map from  $P_0 \oplus \bar{P}_0$  to  $M$  (where the maps along the row of projective modules are the obvious injection and projection for this split exact sequence). Let  $\mu : \bar{P}_0 \rightarrow M$  be a lifting to  $\bar{P}_0$  of the map  $\bar{P}_0 \rightarrow N$  (which exists because  $\bar{P}_0$  is projective). Let  $\lambda$  be the composition  $P_0 \rightarrow L \rightarrow M$  in the diagram. Define

$$\pi : P_0 \oplus \bar{P}_0 \rightarrow M \quad \text{by} \quad \pi(x, y) = \lambda(x) + \mu(y).$$

Show that with this definition the first two nonzero rows of (11) form a commutative diagram.

6. Let  $0 \rightarrow \mathcal{A} \xrightarrow{\alpha} \mathcal{B} \xrightarrow{\beta} \mathcal{C} \rightarrow 0$  be a short exact sequence of cochain complexes. Prove that if any two of  $\mathcal{A}, \mathcal{B}, \mathcal{C}$  are exact, then so is the third. [Use Theorem 2.]
7. Prove that a finitely generated abelian group  $A$  is free if and only if  $\text{Ext}^1(A, \mathbb{Z}) = 0$ .
8. Prove that if  $0 \rightarrow L \rightarrow M \rightarrow N \rightarrow 0$  is a split short exact sequence of  $R$ -modules, then for every  $n \geq 0$  the sequence  $0 \rightarrow \text{Ext}_R^n(N, D) \rightarrow \text{Ext}_R^n(M, D) \rightarrow \text{Ext}_R^n(L, D) \rightarrow 0$  is also short exact and split. [Use a splitting homomorphism and Proposition 5.]
9. Show that

$$0 \longrightarrow \mathbb{Z}/d\mathbb{Z} \longrightarrow \mathbb{Z}/m\mathbb{Z} \xrightarrow{d} \mathbb{Z}/m\mathbb{Z} \xrightarrow{m/d} \mathbb{Z}/m\mathbb{Z} \xrightarrow{d} \mathbb{Z}/m\mathbb{Z} \xrightarrow{m/d} \dots$$

is an injective resolution of  $\mathbb{Z}/d\mathbb{Z}$  as a  $\mathbb{Z}/m\mathbb{Z}$ -module. [Use Proposition 36 in Section 10.5.] Use this to compute the groups  $\text{Ext}_{\mathbb{Z}/m\mathbb{Z}}^n(A, \mathbb{Z}/d\mathbb{Z})$  in terms of the dual group  $\text{Hom}_{\mathbb{Z}/m\mathbb{Z}}(A, \mathbb{Z}/m\mathbb{Z})$ . In particular, if  $m = p^2$  and  $d = p$ , give another derivation of the result  $\text{Ext}_{\mathbb{Z}/p^2\mathbb{Z}}^n(\mathbb{Z}/p\mathbb{Z}, \mathbb{Z}/p\mathbb{Z}) \cong \mathbb{Z}/p\mathbb{Z}$ .

10. (a) Prove that an arbitrary direct sum  $\bigoplus_{i \in I} P_i$  of projective modules  $P_i$  is projective and that an arbitrary direct product  $\prod_{j \in J} Q_j$  of injective modules  $Q_j$  is injective.
- (b) Prove that an arbitrary direct sum of projective resolutions is again projective and use this to show  $\text{Ext}_R^n(\bigoplus_{i \in I} A_i, B) \cong \prod_{i \in I} \text{Ext}_R^n(A_i, B)$  for any collection of  $R$ -modules  $A_i$  ( $i \in I$ ). [cf. Exercise 12 in Section 10.5.]
- (c) Prove that an arbitrary direct product of injective resolutions is an injective resolution and use this to show  $\text{Ext}_R^n(A, \prod_{j \in J} B_j) \cong \prod_{j \in J} \text{Ext}_R^n(A, B_j)$  for any collection of  $R$ -modules  $B_j$  ( $j \in J$ ). [cf. Exercise 12 in Section 10.5.]
- (d) Prove that  $\text{Tor}_n^R(A, \bigoplus_{j \in J} B_j) \cong \bigoplus_{j \in J} \text{Tor}_n^R(A, B_j)$  for any collection of  $R$ -modules  $B_j$  ( $j \in J$ ).
11. (Bass' Characterization of Noetherian Rings) Suppose  $R$  is a commutative ring.
- (a) If  $R$  is Noetherian, and  $I$  is any nonzero ideal in  $R$  show that the image of any  $R$ -module homomorphism  $f : I \rightarrow \bigoplus_{j \in J} Q_j$  from  $I$  into a direct sum of injective  $R$ -modules  $Q_j$  ( $j \in J$ ) is contained in some finite direct sum of the  $Q_j$ .
- (b) If  $R$  is Noetherian, prove that an arbitrary direct sum  $\bigoplus_{j \in J} Q_j$  of injective  $R$ -modules is again injective. [Use Baer's Criterion (Proposition 36) and Exercise 4 in Section 10.5 together with (a).]
- (c) Let  $I_1 \subseteq I_2 \subseteq \dots$  be an ascending chain of ideals of  $R$  with union  $I$  and let  $I/I_i \rightarrow Q_i$  for  $i = 1, 2, \dots$  be an injection of the quotient  $I/I_i$  into an injective  $R$ -module  $Q_i$  (by Theorem 38 in Section 10.5). Prove that the composition of these injections with the product of the canonical projection maps  $I \rightarrow I_i$  gives an  $R$ -module homomorphism  $f : I \rightarrow \bigoplus_{i=1,2,\dots} Q_i$ .
- (d) Prove the converse of (b): if an arbitrary direct sum  $\bigoplus_{j \in J} Q_j$  of injective  $R$ -modules is again injective then  $R$  is Noetherian. [If the direct sum in (c) is injective, use Baer's Criterion to lift  $f$  to a homomorphism  $F : R \rightarrow \bigoplus_{i=1,2,\dots} Q_i$ . If the component of  $F(1)$  in  $Q_i$  is 0 for  $i \geq n$  prove that  $I = I_n$  and the ascending chain of ideals is finite.]
12. Prove Proposition 13:  $\text{Tor}_0^R(D, A) \cong D \otimes_R A$ . [Follow the proof of Proposition 3.]
13. Prove Proposition 16 characterizing flat modules.
14. Suppose  $0 \rightarrow A \rightarrow B \rightarrow C \rightarrow 0$  is a short exact sequence of  $R$ -modules. Prove that if  $C$  is a flat  $R$ -module, then  $A$  is flat if and only if  $B$  is also flat. [Use the Tor long exact sequence.] Give an example to show that if  $A$  and  $B$  are flat then  $C$  need not be flat.

- 15.** (a) If  $I$  is an ideal in  $R$  and  $M$  is an  $R$ -module, prove that  $\text{Tor}_1^R(M, R/I)$  is isomorphic to the kernel of the map  $M \otimes_R I \rightarrow M$  that maps  $m \otimes i$  to  $mi$  for  $i \in I$  and  $m \in M$ . [Use the Tor long exact sequence associated to  $0 \rightarrow I \rightarrow R \rightarrow R/I \rightarrow 0$  noting that  $R$  is flat.]
- (b) (*A Flatness Criterion using Tor*) Prove that the  $R$ -module  $M$  is flat if and only if  $\text{Tor}_1^R(M, R/I) = 0$  for every finitely generated ideal  $I$  of  $R$ . [Use Exercise 25 in Section 10.5.]
- 16.** Suppose  $R$  is a P.I.D. and  $A$  and  $B$  are  $R$ -modules. If  $t(B)$  denotes the torsion submodule of  $B$  show that  $\text{Tor}_1^R(A, t(B)) \cong \text{Tor}_1^R(A, B)$  and deduce that  $\text{Tor}_1^R(A, B)$  is isomorphic to  $\text{Tor}_1^R(t(A), t(B))$ . [Use Exercise 26 in Section 10.5 to show that  $B/t(B)$  is flat over  $R$ , then use the Tor long exact sequence with  $D = A$  applied to the short exact sequence  $0 \rightarrow t(B) \rightarrow B \rightarrow B/t(B) \rightarrow 0$  and the remarks following Proposition 16.]
- 17.** Let  $A = \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z} \oplus \dots$ . Prove that  $\text{Ext}^1(A, B) \cong (B/2B) \times (B/3B) \times (B/4B) \times \dots$  for any abelian group  $A$ . [Use Exercise 10.] Prove that  $\text{Ext}^1(A, B) = 0$  if and only if  $B$  is divisible.
- 18.** Prove that  $\mathbb{Z}/2\mathbb{Z}$  is a projective  $\mathbb{Z}/6\mathbb{Z}$ -module and deduce that  $\text{Tor}_1^{\mathbb{Z}/6\mathbb{Z}}(\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}) = 0$ .
- 19.** Suppose  $r \neq 0$  is not a zero divisor in the commutative ring  $R$ .
- Prove that multiplication by  $r$  gives a free resolution  $0 \rightarrow R \xrightarrow{r} R \rightarrow R/rR \rightarrow 0$  of the quotient  $R/rR$ .
  - Prove that  $\text{Ext}_R^0(R/rR, B) = {}_rB$  is the set of elements  $b \in B$  with  $rb = 0$ , that  $\text{Ext}_R^1(R/rR, B) \cong B/rB$ , and that  $\text{Ext}_R^n(R/rR, B) = 0$  for  $n \geq 2$  for every  $R$ -module  $B$ .
  - Prove that  $\text{Tor}_0^R(A, R/rR) = A/rA$ , that  $\text{Tor}_1^R(A, R/rR) = {}_rA$  is the set of elements  $a \in A$  with  $ra = 0$ , and that  $\text{Tor}_n^R(A, R/rR) = 0$  for  $n \geq 2$  for every  $R$ -module  $A$ .
- 20.** Prove that  $\text{Tor}_0^{\mathbb{Z}/m\mathbb{Z}}(A, \mathbb{Z}/d\mathbb{Z}) \cong A/dA$ , that  $\text{Tor}_n^{\mathbb{Z}/m\mathbb{Z}}(A, \mathbb{Z}/d\mathbb{Z}) \cong {}_dA/(m/d)A$  for  $n$  odd,  $n \geq 1$ , and that  $\text{Tor}_n^{\mathbb{Z}/m\mathbb{Z}}(A, \mathbb{Z}/d\mathbb{Z}) \cong {}_{(m/d)}A/dA$  for  $n$  even,  $n \geq 2$ . [Use the projective resolution in Example 2 following Proposition 3.]
- 21.** Let  $R = k[x, y]$  where  $k$  is a field, and let  $I$  be the ideal  $(x, y)$  in  $R$ .
- Let  $\alpha : R \rightarrow R^2$  be the map  $\alpha(r) = (yr, -xr)$  and let  $\beta : R^2 \rightarrow R$  be the map  $\beta((r_1, r_2)) = r_1x + r_2y$ . Show that
- $$0 \longrightarrow R \xrightarrow{\alpha} R^2 \xrightarrow{\beta} R \longrightarrow k \longrightarrow 0$$
- where the map  $R \rightarrow R/I = k$  is the canonical projection, gives a free resolution of  $k$  as an  $R$ -module.
- Use the resolution in (a) to show that  $\text{Tor}_2^R(k, k) \cong k$ .
  - Prove that  $\text{Tor}_1^R(k, I) \cong k$ . [Use the long exact sequence corresponding to the short exact sequence  $0 \rightarrow I \rightarrow R \rightarrow k \rightarrow 0$  and (b).]
  - Conclude from (c) that the torsion free  $R$ -module  $I$  is not flat (compare to Exercise 26 in Section 10.5).
- 22.** (*Flat Base Change for Tor*) Suppose  $R$  and  $S$  are commutative rings and  $f : R \rightarrow S$  is a ring homomorphism making  $S$  into an  $R$ -module as in Example 6 following Corollary 12 in Section 10.4. Prove that if  $S$  is flat as an  $R$ -module, then  $\text{Tor}_n^R(A, B) \cong \text{Tor}_n^S(S \otimes_R A, B)$  for all  $R$ -modules  $A$  and all  $S$ -modules  $B$ . [Show that since  $S$  is flat, tensoring an  $R$ -module projective resolution for  $A$  with  $S$  gives an  $S$ -module projective resolution of  $S \otimes_R A$ .]

- 23.** (*Localization and Tor*) Let  $D^{-1}R$  be the localization of the commutative ring  $R$  with respect to the multiplicative subset  $D$  of  $R$ . Prove that localization commutes with  $\text{Tor}$ , i.e.,  $D^{-1}\text{Tor}_n^R(A, B) \cong \text{Tor}_n^{D^{-1}R}(D^{-1}A, D^{-1}B)$  for all  $R$ -modules  $A$  and  $B$  and all  $n \geq 0$ . [Use the previous exercise and the fact that  $D^{-1}R$  is flat over  $R$ , cf. Proposition 42(6) in Section 15.4.]
- 24.** (*Flatness is local*) Suppose  $R$  is a commutative ring. Prove that an  $R$ -module  $M$  is flat if and only if every localization  $M_P$  is a flat  $R_P$ -module for every maximal (hence also for every prime) ideal in  $R$ . [Use the previous exercise together with the characterization of flatness in terms of  $\text{Tor}$ .]
- 25.** If  $R$  is an integral domain with field of fractions  $F$ , prove that  $\text{Tor}_1^R(F/R, B) \cong t(B)$  for any  $R$ -module  $B$ , where  $t(B)$  denotes the  $R$ -torsion submodule of  $B$ .

An  $R$ -module  $M$  is said to be *finitely presented* if there is an exact sequence

$$R^s \longrightarrow R^t \longrightarrow M \longrightarrow 0$$

of  $R$ -modules for some integers  $s$  and  $t$ . Equivalently,  $M$  is finitely generated by  $t$  elements and the kernel of the corresponding  $R$ -module homomorphism  $R^t \rightarrow M$  can be generated by  $s$  elements.

- 26.** (a) Prove that every finitely generated module over a Noetherian ring  $R$  is finitely presented. [Use Exercise 8 in Section 15.1.]  
(b) Prove that an  $R$ -module  $M$  is finitely presented and projective if and only if  $M$  is a direct summand of  $R^n$  for some integer  $n \geq 1$ .
- 27.** Suppose that  $M$  is a finitely presented  $R$ -module and that  $0 \rightarrow A \xrightarrow{\alpha} B \xrightarrow{\beta} M \rightarrow 0$  is an exact sequence of  $R$ -modules. This exercise proves that if  $B$  is a finitely generated  $R$ -module then  $A$  is also a finitely generated  $R$ -module.  
(a) Suppose  $R^s \xrightarrow{\psi} R^t \xrightarrow{\varphi} M \rightarrow 0$  and  $e_1, \dots, e_t$  is an  $R$ -module basis for  $R^t$ . Show that there exist  $b_1, \dots, b_t \in B$  so that  $\beta(b_i) = \varphi(e_i)$  for  $i = 1, \dots, t$ .  
(b) If  $f$  is the  $R$ -module homomorphism from  $R^t$  to  $B$  defined by  $f(e_i) = b_i$  for  $i = 1, \dots, t$ , show that  $f(\psi(R^s)) \subseteq \ker \beta$ . [Use  $\varphi \circ \psi = 0$ .] Conclude that there is a commutative diagram

$$\begin{array}{ccccccc} & & \psi & & \varphi & & \\ R^s & \longrightarrow & R^t & \longrightarrow & M & \longrightarrow & 0 \\ g \downarrow & & f \downarrow & & \parallel & & \\ 0 & \longrightarrow & A & \xrightarrow{\alpha} & B & \xrightarrow{\beta} & M \longrightarrow 0 \end{array}$$

of  $R$ -modules with exact rows.

- (c) Prove that  $A/\text{image } g \cong B/\text{image } f$  and use this to prove that  $A$  is finitely generated. [For the isomorphism, use the Snake Lemma in Exercise 3. Then show that  $\text{image } g$  and  $A/\text{image } g$  are both finitely generated and apply Exercise 7 of Section 10.3.]  
(d) If  $I$  is an ideal of  $R$  conclude that  $R/I$  is a finitely presented  $R$ -module if and only if  $I$  is a finitely generated ideal.
- 28.** Suppose  $R$  is a local ring with unique maximal ideal  $\mathfrak{m}$  and  $M$  is a finitely presented  $R$ -module. Suppose  $m_1, \dots, m_s$  are elements in  $M$  whose images in  $M/\mathfrak{m}M$  form a basis for  $M/\mathfrak{m}M$  as a vector space over the field  $R/\mathfrak{m}$ .  
(a) Prove that  $m_1, \dots, m_s$  generate  $M$  as an  $R$ -module. [Use Nakayama's Lemma.]  
(b) Conclude from (a) that there is an exact sequence  $0 \rightarrow \ker \varphi \rightarrow R^s \xrightarrow{\varphi} M \rightarrow 0$  that maps a set of free generators of  $R^s$  to the elements  $m_1, \dots, m_s$ . Deduce that there is

an exact sequence

$$\mathrm{Tor}_1^R(M, R/\mathfrak{m}) \longrightarrow (\ker \varphi)/\mathfrak{m}(\ker \varphi) \longrightarrow 0.$$

[Use the Tor long exact sequence with respect to tensoring with  $R/\mathfrak{m}$ , using the fact that  $N \otimes R/\mathfrak{m} \cong N/\mathfrak{m}N$  for any  $R$ -module  $N$  (Example 8 following Corollary 12 in Section 10.4) and the fact that  $\varphi : (R/\mathfrak{m})^s \cong M/\mathfrak{m}M$  is an isomorphism by the choice of  $m_1, \dots, m_s$ .]

- (c) Prove that if  $\mathrm{Tor}_1^R(M, R/\mathfrak{m}) = 0$  then  $m_1, \dots, m_s$  are a set of free  $R$ -module generators for  $M$ . [Use the previous exercise and Nakayama's Lemma to show that  $\ker \varphi = 0$ .]

29. Suppose  $R$  is a local ring with unique maximal ideal  $\mathfrak{m}$ . This exercise proves that a finitely generated  $R$ -module is flat if and only if it is free.

- (a) Prove that  $M = F/K$  is the quotient of a finitely generated free module  $F$  by a submodule  $K$  with  $K \subseteq \mathfrak{m}F$ . [Let  $F$  be a free module with  $F/\mathfrak{m}F \cong M/\mathfrak{m}M$ .]
- (b) Suppose  $x \in K$  and write  $x = a_1e_1 + \dots + a_ne_n$  where  $e_1, \dots, e_n$  are an  $R$ -basis for  $F$ . Let  $I = (a_1, \dots, a_n)$  be the ideal of  $R$  generated by  $a_1, \dots, a_n$ . Prove that if  $M$  is flat, then  $I = \mathfrak{m}I$  and deduce that  $K = 0$ , so  $M$  is free. [Use Exercise 25(d) of Section 10.5 to see that  $x \in IK \subseteq \mathfrak{m}I$  and conclude that  $I \subseteq \mathfrak{m}I$ . Then apply Nakayama's Lemma to the finitely generated ideal  $I$ .]

30. Suppose  $R$  is a local ring with unique maximal ideal  $\mathfrak{m}$ ,  $M$  is an  $R$ -module, and consider the following statements:

- (i)  $M$  is a free  $R$ -module,
  - (ii)  $M$  is a projective  $R$ -module,
  - (iii)  $M$  is a flat  $R$ -module, and
  - (iv)  $\mathrm{Tor}_1^R(M, R/\mathfrak{m}) = 0$ .
- (a) Prove that (i) implies (ii) implies (iii) implies (iv).
- (b) Prove that (i), (ii), and (iii) are equivalent if  $M$  is finitely generated. (Exercise 34 below shows (iii) need not imply (i) or (ii) if  $M$  is finitely generated but  $R$  is not local.) [Use the previous exercise.]
- (c) Prove that (i), (ii), (iii), and (iv) are equivalent if  $M$  is finitely presented. (Exercise 35 below shows that (iv) need not imply (i), (ii) or (iii) if  $M$  is finitely generated but not finitely presented.) [Use Exercise 28.]

*Remark:* It is a theorem of Kaplansky (cf. *Projective Modules*, Annals of Mathematics, 68(1958), pp. 372–377) that (i) and (ii) are equivalent without the condition that  $M$  be finitely generated.

31. (*Localization and Hom for Finitely Presented Modules*) Suppose  $D^{-1}R$  is the localization of the commutative ring  $R$  with respect to the multiplicative subset  $D$  of  $R$ , and let  $M$  be a finitely presented  $R$ -module.

- (a) For any  $R$ -modules  $A$  and  $B$  prove there is a unique  $D^{-1}R$ -module homomorphism from  $D^{-1}\mathrm{Hom}_R(A, B)$  to  $\mathrm{Hom}_{D^{-1}R}(D^{-1}A, D^{-1}B)$  that maps  $\varphi \in \mathrm{Hom}_R(A, B)$  to the homomorphism from  $D^{-1}A$  to  $D^{-1}B$  induced by  $\varphi$ .
- (b) For any  $R$ -module  $N$  and any  $m \geq 1$  show that  $\mathrm{Hom}_R(R^m, N) \cong N^m$  as  $R$ -modules and deduce that  $D^{-1}\mathrm{Hom}_R(R^m, N) \cong (D^{-1}N)^m$  as  $D^{-1}R$ -modules.
- (c) Suppose  $R^s \rightarrow R^t \rightarrow M \rightarrow 0$  is exact. Prove there is a commutative diagram

$$\begin{array}{ccccccc}
 0 \rightarrow & D^{-1}\mathrm{Hom}_R(M, N) & \rightarrow & D^{-1}\mathrm{Hom}_R(R^t, N) & \rightarrow & D^{-1}\mathrm{Hom}_R(R^s, N) & \\
 & \downarrow & & \downarrow & & \downarrow & \\
 0 \rightarrow & \mathrm{Hom}_{D^{-1}R}(D^{-1}M, D^{-1}N) & \rightarrow & \mathrm{Hom}_{D^{-1}R}((D^{-1}R)^t, D^{-1}N) & \rightarrow & \mathrm{Hom}_{D^{-1}R}((D^{-1}R)^s, D^{-1}N) &
 \end{array}$$

of  $D^{-1}R$ -modules with exact rows. [For the first row first take  $R$ -module homomor-

phisms from the terms in the presentation for  $M$  into  $N$  using Theorem 33 of Section 10.5 (noting the first comment in the proof) and then tensor with the flat  $R$ -module  $D^{-1}R$ , cf. Propositions 41 and 42(6) in Section 15.4. For the second row first tensor the presentation with  $D^{-1}R$  and then take  $D^{-1}R$ -module homomorphisms into  $D^{-1}N$ .]

- (d) Use (b) to prove that localization commutes with taking homomorphisms when  $M$  is finitely presented, i.e.,  $D^{-1}\text{Hom}_R(M, N) \cong \text{Hom}_{D^{-1}R}(D^{-1}M, D^{-1}N)$  as  $D^{-1}R$ -modules. [Show the second two vertical maps in the diagram above are isomorphisms and deduce that the left vertical map is also an isomorphism.] (This result is not true in general if  $M$  is not finitely presented.)
32. (*Localization and Ext for Finitely Presented Modules*) Suppose  $D^{-1}R$  is the localization of the commutative ring  $R$  with respect to the multiplicative subset  $D$  of  $R$ . Prove that if  $M$  is a finitely presented  $R$ -module then  $D^{-1}\text{Ext}_R^n(M, N) \cong \text{Ext}_{D^{-1}R}^n(D^{-1}M, D^{-1}N)$  as  $D^{-1}R$ -modules for every  $R$ -module  $N$  and every  $n \geq 0$ . [Use a projective resolution of  $N$  and the previous exercise, noting that tensoring the resolution with  $D^{-1}R$  gives a projective resolution for the  $D^{-1}R$ -module  $D^{-1}N$ .]
33. Suppose  $R$  is a commutative ring and  $M$  is a finitely presented  $R$ -module (for example a finitely generated module over a Noetherian ring, or a quotient,  $R/I$ , of  $R$  by a finitely generated ideal  $I$ , cf. Exercises 26 and 27). Prove that the following are equivalent:
- (a)  $M$  is a projective  $R$ -module,
  - (b)  $M$  is a flat  $R$ -module,
  - (c)  $M$  is locally free, i.e., each localization  $M_P$  is a free  $R_P$ -module for every maximal (hence also for every prime) ideal  $P$  of  $R$ .
- In particular show that finitely generated projective modules are the same as finitely presented flat modules. [Exercises 24 and 30 show that (b) is equivalent to (c). Use the Ext criterion for projectivity and Exercises 30 and 32 to see that (a) is equivalent to (c).]
34. (a) Prove that *every*  $R$ -module for the commutative ring  $R$  is flat if and only if *every* finitely generated ideal  $I$  of  $R$  is a direct summand of  $R$ , in which case every finitely generated ideal of  $R$  is principal and projective (such a ring is said to be *absolutely flat*). [Use Exercise 15, the previous exercise applied to the finitely presented  $R$ -module  $R/I$ , and the remarks following Proposition 16.]
- (b) Prove that every Boolean ring is absolutely flat. [Use Exercise 24 in Section 7.4, noting that if  $I = Rx$  then  $x$  is an idempotent so  $R = Rx \oplus R(1-x)$ .]
- (c) Let  $R$  be the direct product and  $I$  the direct sum of countably many copies of  $\mathbb{Z}/2\mathbb{Z}$ . Prove that  $I$  is an ideal of the Boolean ring  $R$  that is not finitely generated and that the cyclic  $R$ -module  $M = R/I$  is flat but not projective (so finitely generated flat modules need not be projective).
35. Let  $R$  be the local ring obtained by localizing the ring of  $C^\infty$  functions on the open interval  $(-1, 1)$  at the maximal ideal of functions that are 0 at  $x = 0$  (cf. Exercise 45 of Section 15.2), let  $\mathfrak{m} = (x)$  be the unique maximal ideal of  $R$  and let  $P$  be the prime ideal  $\cap_{n \geq 1} \mathfrak{m}^n$ . Set  $M = R/P$ .
- (a) Prove that  $\text{Tor}_1^R(M, R/\mathfrak{m}) = 0$ . [Use Exercise 19 applied with  $r = x$ , noting that  $R/P$  is an integral domain.]
  - (b) Prove that  $M$  is not flat (hence not projective). [Let  $F$  be as in Exercise 45 of Section 15.2. Show that the sequence  $0 \rightarrow R \rightarrow R \rightarrow R/(F) \rightarrow 0$  induced by multiplication by  $F$  is exact, but is not exact after tensoring with  $M$ .]

## 17.2 THE COHOMOLOGY OF GROUPS

In this section we consider the application of the general techniques of the previous section in an important special case.

Let  $G$  be a group.

**Definition.** An abelian group  $A$  on which  $G$  acts (on the left) as automorphisms is called a  *$G$ -module*.

Note that a  $G$ -module is the same as an abelian group  $A$  and a homomorphism  $\varphi : G \rightarrow \text{Aut}(A)$  of  $G$  into the group of automorphisms of  $A$ . Since an abelian group is the same as a module over  $\mathbb{Z}$ , it is also easy to see that a  $G$ -module  $A$  is the same as a module over the integral group ring  $\mathbb{Z}G$ , of  $G$  with coefficients in  $\mathbb{Z}$ . When  $G$  is an infinite group the ring  $\mathbb{Z}G$  consists of all the finite formal sums of elements of  $G$  with coefficients in  $\mathbb{Z}$ .

As usual we shall often use multiplicative notation and write  $ga$  in place of  $g \cdot a$  for the action of the element  $g \in G$  on the element  $a \in A$ .

**Definition.** If  $A$  is a  $G$ -module, let  $A^G = \{a \in A \mid ga = a \text{ for all } g \in G\}$  be the elements of  $A$  fixed by all the elements of  $G$ .

### Examples

- (1) If  $ga = a$  for all  $a \in A$  and  $g \in G$  then  $G$  is said to act *trivially* on  $A$ . In this case  $A^G = A$ . The abelian group  $\mathbb{Z}$  will always be assumed to have trivial  $G$ -action for any group  $G$  unless otherwise stated.
- (2) For any  $G$ -module  $A$  the fixed points  $A^G$  of  $A$  under the action of  $G$  is clearly a  $\mathbb{Z}G$ -submodule of  $A$  on which  $G$  acts trivially.
- (3) If  $V$  is a vector space over the field  $F$  of dimension  $n$  and  $G = GL_n(F)$  then  $V$  is naturally a  $G$ -module. In this case  $V^G = \{0\}$  since any nonzero element in  $V$  can be taken to any other nonzero element in  $V$  by some linear transformation.
- (4) A semidirect product  $E = A \rtimes G$  as in Section 5.5 in the case where  $A$  is an abelian normal subgroup gives a  $G$ -module  $A$  where the action of  $G$  is given by the homomorphism  $\varphi : G \rightarrow \text{Aut}(A)$ . The subgroup  $A^G$  consists of the elements of  $A$  lying in the center of  $E$ . More generally, if  $A$  is any abelian normal subgroup of a group  $E$ , then  $E$  acts on  $A$  by conjugation and this makes  $A$  into a  $E$ -module and also an  $E/A$ -module. In this case  $A^E = A^{E/A}$  also consists of the elements of  $A$  lying in the center of  $E$ .
- (5) If  $K/F$  is an extension of fields that is Galois with Galois group  $G$  then the additive group  $K$  is naturally a  $G$ -module, with  $K^G = F$ . Similarly, the multiplicative group  $K^\times$  of nonzero elements in  $K$  is a  $G$ -module, with fixed points  $(K^\times)^G = F^\times$ .

The fixed point subgroups in this last example played a central role in Galois Theory in Chapter 14. In general, it is easy to see that a short exact sequence

$$0 \longrightarrow A \longrightarrow B \longrightarrow C \longrightarrow 0$$

of  $G$ -modules induces an exact sequence

$$0 \longrightarrow A^G \longrightarrow B^G \longrightarrow C^G \tag{17.15}$$

that in general cannot be extended to a short exact sequence (in general a coset in the quotient  $C$  that is fixed by  $G$  need not be represented by an *element* in  $B$  fixed by  $G$ ). One way to see that (15) is exact is to observe that  $A^G$  can be related to a Hom group:

**Lemma 19.** Suppose  $A$  is a  $G$ -module and  $\text{Hom}_{\mathbb{Z}G}(\mathbb{Z}, A)$  is the group of all  $\mathbb{Z}G$ -module homomorphisms from  $\mathbb{Z}$  (with trivial  $G$ -action) to  $A$ . Then  $A^G \cong \text{Hom}_{\mathbb{Z}G}(\mathbb{Z}, A)$ .

*Proof:* Any  $G$ -module homomorphism  $\alpha$  from  $\mathbb{Z}$  to  $A$  is uniquely determined by its value on 1. Let  $\alpha_a$  denote the  $G$ -module homomorphism with  $\alpha(1) = a$ . Since  $\alpha_a$  is a  $G$ -module homomorphism,  $a = \alpha_a(1) = \alpha_a(g \cdot 1) = g \cdot \alpha_a(1) = g \cdot a$  for all  $g \in G$ , so that  $a$  must lie in  $A^G$ . Likewise, for any  $a \in A^G$  it is easy to check that the map  $\alpha_a \mapsto a$  gives an isomorphism from  $\text{Hom}_{\mathbb{Z}G}(\mathbb{Z}, A)$  to  $A^G$ .

Combined with the results of the previous section, the lemma not only shows that the sequence (15) is exact, it shows that any projective resolution of  $\mathbb{Z}$  considered as a  $\mathbb{Z}G$ -module will give a long exact sequence extending (15). One such projective resolution is the *standard resolution* or *bar resolution* of  $\mathbb{Z}$ :

$$\cdots \longrightarrow F_n \xrightarrow{d_n} F_{n-1} \rightarrow \cdots \xrightarrow{d_1} F_0 \xrightarrow{\text{aug}} \mathbb{Z} \longrightarrow 0. \quad (17.16)$$

Here  $F_n = \mathbb{Z}G \otimes_{\mathbb{Z}} \mathbb{Z}G \otimes_{\mathbb{Z}} \cdots \otimes_{\mathbb{Z}} \mathbb{Z}G$  (where there are  $n+1$  factors) for  $n \geq 0$ , which is a  $G$ -module under the action defined on simple tensors by  $g \cdot (g_0 \otimes g_1 \otimes \cdots \otimes g_n) = (gg_0) \otimes g_1 \otimes \cdots \otimes g_n$ . It is not difficult to see that  $F_n$  is a free  $\mathbb{Z}G$ -module of rank  $|G|^n$  with  $\mathbb{Z}G$  basis given by the elements  $1 \otimes g_1 \otimes g_2 \otimes \cdots \otimes g_n$ , where  $g_i \in G$ . The map  $\text{aug} : F_0 \rightarrow \mathbb{Z}$  is the *augmentation map*  $\text{aug}(\sum_{g \in G} \alpha_g g) = \sum_{g \in G} \alpha_g$ , and the map  $d_1$  is given by  $d_1(1 \otimes g) = g - 1$ . The maps  $d_n$  for  $n \geq 2$  are more complicated and their definition, together with a proof that (16) is a projective (in fact, free) resolution can be found in Exercises 1–3.

Applying ( $\mathbb{Z}G$ -module) homomorphisms from the terms in (16) to the  $G$ -module  $A$  (replacing the first term by 0) as in the previous section, we obtain the cochain complex

$$0 \longrightarrow \text{Hom}_{\mathbb{Z}G}(F_0, A) \xrightarrow{d_1} \text{Hom}_{\mathbb{Z}G}(F_1, A) \xrightarrow{d_2} \text{Hom}_{\mathbb{Z}G}(F_2, A) \xrightarrow{d_3} \cdots, \quad (17.17)$$

the cohomology groups of which are, by definition, the groups  $\text{Ext}_{\mathbb{Z}G}^n(\mathbb{Z}, A)$ . Then, as in Theorem 8, the short exact sequence  $0 \longrightarrow A \longrightarrow B \longrightarrow C \longrightarrow 0$  of  $G$ -modules gives rise to a long exact sequence whose first terms are given by (15) and whose higher terms are the cohomology groups  $\text{Ext}_{\mathbb{Z}G}^n(\mathbb{Z}, A)$ .

To make this more explicit, we can reinterpret the terms in this cochain complex without explicit reference to the standard resolution of  $\mathbb{Z}$ , as follows. The elements of  $\text{Hom}_{\mathbb{Z}G}(F_n, A)$  are uniquely determined by their values on the  $\mathbb{Z}G$  basis elements of  $F_n$ , which may be identified with the  $n$ -tuples  $(g_1, g_2, \dots, g_n)$  of elements  $g_i$  of  $G$ . It follows for  $n \geq 1$  that the group  $\text{Hom}_{\mathbb{Z}G}(F_n, A)$  may be identified with the set of functions from  $G \times \cdots \times G$  ( $n$  copies) to  $A$ . For  $n = 0$  we identify  $\text{Hom}_{\mathbb{Z}G}(\mathbb{Z}G, A)$  with  $A$ .

**Definition.** If  $G$  is a finite group and  $A$  is a  $G$ -module, define  $C^0(G, A) = A$  and for  $n \geq 1$  define  $C^n(G, A)$  to be the collection of all maps from  $G^n = G \times \cdots \times G$  ( $n$  copies) to  $A$ . The elements of  $C^n(G, A)$  are called *n-cochains* (of  $G$  with values in  $A$ ).

Each  $C^n(G, A)$  is an additive abelian group: for  $C^0(G, A) = A$  given by the group structure on  $A$ ; for  $n \geq 1$  given by the usual pointwise addition of functions:  $(f_1 + f_2)(g_1, g_2, \dots, g_n) = f_1(g_1, g_2, \dots, g_n) + f_2(g_1, g_2, \dots, g_n)$ . Under the identification of  $\text{Hom}_{\mathbb{Z}G}(F_n, A)$  with  $C^n(G, A)$  the cochain maps  $d_n$  in (17) can be given very explicitly (cf. also Exercise 3 and the following comment):

**Definition.** For  $n \geq 0$ , define the  $n^{\text{th}}$  *coboundary* homomorphism from  $C^n(G, A)$  to  $C^{n+1}(G, A)$  by

$$\begin{aligned} d_n(f)(g_1, \dots, g_{n+1}) &= g_1 \cdot f(g_2, \dots, g_{n+1}) \\ &+ \sum_{i=1}^n (-1)^i f(g_1, \dots, g_{i-1}, g_i g_{i+1}, g_{i+2}, \dots, g_{n+1}) \\ &+ (-1)^{n+1} f(g_1, \dots, g_n) \end{aligned} \quad (17.18)$$

where the product  $g_i g_{i+1}$  occupying the  $i^{\text{th}}$  position of  $f$  is taken in the group  $G$ .

It is immediate from the definition that the maps  $d_n$  are group homomorphisms. It follows from the fact that (17) is a projective resolution that  $d_n \circ d_{n-1} = 0$  for  $n \geq 1$  (a self contained direct proof just from the definition of  $d_n$  above can also be given, but is tedious).

### Definition.

- (1) Let  $Z^n(G, A) = \ker d_n$  for  $n \geq 0$ . The elements of  $Z^n(G, A)$  are called  $n$ -cocycles.
- (2) Let  $B^n(G, A) = \text{image } d_{n-1}$  for  $n \geq 1$  and let  $B^0(G, A) = 1$ . The elements of  $B^n(G, A)$  are called  $n$ -coboundaries.

Since  $d_n \circ d_{n-1} = 0$  for  $n \geq 1$  we have  $\text{image } d_{n-1} \subseteq \ker d_n$ , so that  $B^n(G, A)$  is always a subgroup of  $Z^n(G, A)$ .

**Definition.** For any  $G$ -module  $A$  the quotient group  $Z^n(G, A)/B^n(G, A)$  is called the  $n^{\text{th}}$  *cohomology group of  $G$  with coefficients in  $A$*  and is denoted by  $H^n(G, A)$ ,  $n \geq 0$ .

The definition of the cohomology group  $H^n(G, A)$  in terms of cochains will be particularly useful in the following two sections when we examine the low dimensional groups  $H^1(G, A)$  and  $H^2(G, A)$  and their application in a variety of settings. It should be remembered, however, that  $H^n(G, A) \cong \text{Ext}^n(\mathbb{Z}, A)$  for all  $n \geq 0$ . In particular, these groups can be computed using *any* projective resolution of  $\mathbb{Z}$ .

### Examples

- (1) For  $f = a \in C^0(G, A)$  we have  $d_0(f)(g) = g \cdot a - a$  and so  $\ker d_0$  is the set  $\{a \in A \mid g \cdot a = a \text{ for all } g \in G\}$ , i.e.,  $Z^0(G, A) = A^G$  and so

$$H^0(G, A) = A^G,$$

for any group  $G$  and  $G$ -module  $A$ .

- (2) Suppose  $G = 1$  is the trivial group. Then  $G^n = \{(1, 1, \dots, 1)\}$  is also the trivial group, so  $f \in C^n(G, A)$  is completely determined by  $f(1, 1, \dots, 1) = a \in A$ . Identifying  $f = a$  we obtain  $C^n(G, A) = A$  for all  $n \geq 0$ . Then, if  $f = a \in A$ ,

$$d_n(f)(1, 1, \dots, 1) = a + \sum_{i=1}^n (-1)^i a + (-1)^{n+1} a = \begin{cases} 0 & \text{if } n \text{ is even} \\ 1 & \text{if } n \text{ is odd} \end{cases},$$

so  $d_n = 0$  if  $n$  is even and  $d_n = 1$  is the identity if  $n$  is odd. Hence

$$H^0(1, A) = A^G = A$$

$$H^n(1, A) = 0 \text{ for all } n \geq 1.$$

### Example: (Cohomology of a Finite Cyclic Group)

Suppose  $G$  is cyclic of order  $m$  with generator  $\sigma$ . Let  $N = 1 + \sigma + \sigma^2 + \dots + \sigma^{m-1} \in \mathbb{Z}G$ . Then  $N(\sigma - 1) = (\sigma - 1)N = \sigma^m - 1 = 0$ , and so we have a particularly simple free resolution

$$\dots \xrightarrow{\sigma-1} \mathbb{Z}G \xrightarrow{N} \mathbb{Z}G \xrightarrow{\sigma-1} \dots \xrightarrow{N} \mathbb{Z}G \xrightarrow{\sigma-1} \mathbb{Z}G \xrightarrow{\text{aug}} \mathbb{Z} \longrightarrow 0$$

where aug denotes the augmentation map (cf. Exercise 8). Taking  $\mathbb{Z}G$ -module homomorphisms from the terms of this resolution to  $A$  (replacing the first term by 0) and using the identification  $\text{Hom}_{\mathbb{Z}G}(\mathbb{Z}G, A) = A$  gives the chain complex

$$0 \longrightarrow A \xrightarrow{\sigma-1} A \xrightarrow{N} A \xrightarrow{\sigma-1} A \xrightarrow{N} \dots$$

whose cohomology computes the groups  $H^n(G, A)$ :

$$H^0(G, A) = A^G, \text{ and } H^n(G, A) = \begin{cases} A^G/NA & \text{if } n \text{ is even, } n \geq 2 \\ NA/(\sigma - 1)A & \text{if } n \text{ is odd, } n \geq 1 \end{cases}$$

where  $NA = \{a \in A \mid Na = 0\}$  is the subgroup of  $A$  annihilated by  $N$ , since the kernel of multiplication by  $\sigma - 1$  is  $A^G$ .

If in particular  $G = \langle \sigma \rangle$  acts trivially on  $A$ , then  $N \cdot a = ma$ , so that in this case  $H^0(G, A) = A$ , with  $H^n(G, A) = A/mA$  for even  $n \geq 2$ , and  $H^n(G, A) = mA$ , the elements of  $A$  of order dividing  $m$ , for odd  $n \geq 1$ . Specializing even further to  $m = 1$  gives Example 2 previously.

**Proposition 20.** Suppose  $mA = 0$  for some integer  $m \geq 1$  (i.e., the  $G$ -module  $A$  has exponent dividing  $m$  as an abelian group). Then

$$mZ^n(G, A) = mB^n(G, A) = mH^n(G, A) = 0 \quad \text{for all } n \geq 0.$$

In particular, if  $A$  has exponent  $p$  for some prime  $p$  then the abelian groups  $Z^n(G, A)$ ,  $B^n(G, A)$  and  $H^n(G, A)$  have exponent dividing  $p$  and so these groups are all vector spaces over the finite field  $\mathbb{F}_p = \mathbb{Z}/p\mathbb{Z}$ .

*Proof:* If  $f \in C^n(G, A)$  is an  $n$ -cochain then  $f \in A$  (if  $n = 0$ ), in which case  $mf = 0$ , or  $f$  is a function from  $G^n$  to  $A$  (if  $n \geq 1$ ), in which case  $mf$  is a function from  $G^n$  to  $mA = 0$ , so again  $mf = 0$ . Hence  $mZ^n(G, A) = mB^n(G, A) = 0$  since these are subgroups of  $C^n(G, A)$ . Then  $mH^n(G, A) = 0$  since  $mZ^n(G, A) = 0$ , and the remaining statements in the proposition are immediate.

By Example 1, the long exact sequence in Theorem 10 written in terms of the cohomology groups  $H^n(G, A)$  becomes

**Theorem 21.** (*Long Exact Sequence in Group Cohomology*) Suppose

$$0 \longrightarrow A \longrightarrow B \longrightarrow C \longrightarrow 0$$

is a short exact sequence of  $G$ -modules. Then there is a long exact sequence:

$$\begin{aligned} 0 \longrightarrow A^G \longrightarrow B^G \longrightarrow C^G &\xrightarrow{\delta_0} H^1(G, A) \longrightarrow H^1(G, B) \longrightarrow H^1(G, C) \xrightarrow{\delta_1} \cdots \\ \cdots &\xrightarrow{\delta_{n-1}} H^n(G, A) \longrightarrow H^n(G, B) \longrightarrow H^n(G, C) \xrightarrow{\delta_n} H^{n+1}(G, A) \longrightarrow \cdots \end{aligned}$$

of abelian groups.

Among many other uses of the long exact sequence in Theorem 21 is a technique called *dimension shifting* which makes it possible to analyze the cohomology group  $H^{n+1}(G, A)$  of dimension  $n + 1$  for  $A$  by instead considering a cohomology group of dimension  $n$  for a different  $G$ -module. The technique is based on finding a  $G$ -module almost all of whose cohomology groups are zero. Such modules are given a name:

**Definition.** A  $G$ -module  $M$  is called *cohomologically trivial* for  $G$  if  $H^n(G, M) = 0$  for all  $n \geq 1$ .

**Corollary 22.** (*Dimension Shifting*) Suppose  $0 \rightarrow A \rightarrow M \rightarrow C \rightarrow 0$  is a short exact sequence of  $G$ -modules and that  $M$  is cohomologically trivial for  $G$ . Then there is an exact sequence

$$0 \longrightarrow A^G \longrightarrow M^G \longrightarrow C^G \longrightarrow H^1(G, A) \longrightarrow 0$$

and

$$H^{n+1}(G, A) \cong H^n(G, C) \text{ for all } n \geq 1.$$

*Proof:* Since  $M$  is cohomologically trivial for  $G$ , the portion

$$H^n(G, M) \longrightarrow H^n(G, C) \longrightarrow H^{n+1}(G, A) \longrightarrow H^{n+1}(G, M)$$

of the long exact sequence in Theorem 21 reduces to

$$0 \longrightarrow H^n(G, C) \longrightarrow H^{n+1}(G, A) \longrightarrow 0$$

which shows that  $H^n(G, C) \cong H^{n+1}(G, A)$  for  $n \geq 1$ . Similarly, the first portion of the long exact sequence in Theorem 21 gives the first statement in the corollary.

We now indicate a natural construction that produces a  $G$ -module given a module over a subgroup  $H$  of  $G$ . When  $H = 1$  is the trivial group this construction produces a cohomologically trivial module  $M$  and an exact sequence as in Corollary 22 for any  $G$ -module  $A$ .

**Definition.** If  $H$  is a subgroup of  $G$  and  $A$  is an  $H$ -module, define the *induced  $G$ -module*  $M_H^G(A)$  to be  $\text{Hom}_{\mathbb{Z}H}(\mathbb{Z}G, A)$ . In other words,  $M_H^G(A)$  is the set of maps  $f$  from  $G$  to  $A$  satisfying  $f(hx) = hf(x)$  for every  $x \in G$  and  $h \in H$ .

The action of an element  $g \in G$  on  $f \in M_H^G(A)$  is given by  $(g \cdot f)(x) = f(xg)$  for  $x \in G$  (cf. Exercise 10 in Section 10.5).

Recall that if  $H$  is a subgroup of  $G$  and  $A$  is an  $H$ -module, then the module  $\mathbb{Z}G \otimes_{\mathbb{Z}H} A$  obtained by extension of scalars from  $\mathbb{Z}H$  to  $\mathbb{Z}G$  is a  $G$ -module. For a finite group  $G$ , or more generally if  $H$  has finite index in  $G$ , we have  $M_H^G(A) \cong \mathbb{Z}G \otimes_{\mathbb{Z}H} A$  (cf. Exercise 10). When  $G$  is infinite this need no longer be the case (cf. Exercise 11). The module  $\mathbb{Z}G \otimes_{\mathbb{Z}H} A$  is sometimes called the *induced  $G$ -module* and the module  $M_H^G(A)$  is sometimes referred to as the *coinduced  $G$ -module*. For finite groups, associativity of the tensor product shows that  $M_H^G(M_K^H(A)) = M_K^G(A)$  for subgroups  $K \leq H \leq G$ , and the same result holds in general (this follows from the definition using Exercise 7).

## Examples

- (1) If  $H$  is a subgroup of  $G$  and  $0 \rightarrow A \rightarrow B \rightarrow C \rightarrow 0$  is a short exact sequence of  $H$ -modules then  $0 \rightarrow M_H^G(A) \rightarrow M_H^G(B) \rightarrow M_H^G(C) \rightarrow 0$  is a short exact sequence of  $G$ -modules, since  $M_H^G(A) \cong \mathbb{Z}G \otimes_{\mathbb{Z}H} A$  and  $\mathbb{Z}G$  is free, hence flat, over  $\mathbb{Z}H$ .
- (2) When  $G$  is finite and  $A$  is the trivial  $H$ -module  $\mathbb{Z}$ , the module  $M_H^G(\mathbb{Z})$  is a free  $\mathbb{Z}$ -module of rank  $m = |G : H|$ . There is a basis  $b_1, \dots, b_m$  such that  $G$  permutes these basis elements in the same way it permutes the left cosets of  $H$  in  $G$  by left multiplication, i.e., if we let  $b_i \leftrightarrow g_i H$  then  $gb_i = b_j$  if and only if  $gg_i H = g_j H$ . The module  $M_H^G(\mathbb{Z})$  is the *permutation module* over  $\mathbb{Z}$  for  $G$  with stabilizer  $H$ . A special case of interest is when  $G = S_m$  and  $H = S_{m-1}$  where  $S_m$  permutes  $\{1, 2, \dots, m\}$  as usual. Permutation modules and induced modules over fields are studied in Part VI.
- (3) Any abelian group  $A$  is an  $H$ -module when  $H = 1$  is the trivial group. The corresponding induced  $G$ -module  $M_1^G(A)$  is just the collection of all maps  $f$  from  $G$  into  $A$ . For  $g \in G$  the map  $g \cdot f \in M_1^G(A)$  satisfies  $(g \cdot f)(x) = f(xg)$  for  $x \in G$ .
- (4) Suppose  $A$  is a  $G$ -module. Then there is a natural map

$$\varphi : A \longrightarrow M_1^G(A)$$

from  $A$  into the induced  $G$ -module  $M_1^G(A)$  in the previous example defined by mapping  $a \in A$  to the function  $f_a$  with  $f_a(x) = xa$  for all  $x \in G$ . It is clear that  $\varphi$  is a group homomorphism, and  $f_{ga}(x) = x(ga) = (xg)a = f_a(xg) = (g \cdot f_a)(x)$  shows that  $\varphi$  is a  $G$ -module homomorphism as well. Since  $f_a(1) = a$ , it follows that  $f_a$  is the zero function on  $G$  if and only if  $a = 0$  in  $A$ , so that  $\varphi$  is an injection. Hence we may identify  $A$  as a  $G$ -submodule of the induced module  $M_1^G(A)$ .

- (5) More generally, if  $A$  is a  $G$ -module and  $H$  is any subgroup of  $G$  then the function  $f_a(x)$  in the previous example is an element in the subgroup  $M_H^G(A)$  since we have  $f_a(hx) = (hx)(a) = h(xa) = hf_a(x)$  for all  $h \in H$ . The associated map from  $A$  to  $M_H^G(A)$  is an injective  $G$ -module homomorphism.
- (6) The fixed points  $(M_H^G(A))^G$  are maps  $f$  from  $G$  to  $A$  with  $gf = f$  for all  $g \in G$ , i.e., with  $(gf)(x) = f(x)$  for all  $g, x \in G$ . By definition of the  $G$ -action on  $M_H^G(A)$ , this is the equation  $f(xg) = f(x)$  for all  $g, x \in G$ . Taking  $x = 1$  shows that  $f$  is constant on all of  $G$ :  $f(g) = f(1) = a \in A$ . The constant function  $f = a$  is an element of  $M_H^G(A)$  if and only if  $a = f(hx) = hf(x) = ha$  for all  $h \in H$ , so  $(M_H^G(A))^G \cong A^H$ .

An element  $f_a(x)$  in the previous example is contained in the subgroup  $(M_H^G(A))^G$  if and only if  $xa$  is constant for  $x \in G$ , i.e., if and only if  $a \in A^G$ .

One of the important properties of the  $G$ -module  $M_H^G(A)$  induced from the  $H$ -module  $A$  is that its cohomology with respect to  $G$  is the same as the cohomology of  $A$  with respect to  $H$ :

**Proposition 23.** (*Shapiro's Lemma*) For any subgroup  $H$  of  $G$  and any  $H$ -module  $A$  we have  $H^n(G, M_H^G(A)) \cong H^n(H, A)$  for  $n \geq 0$ .

*Proof:* Let  $\cdots \rightarrow P_n \rightarrow \cdots \rightarrow P_0 \rightarrow \mathbb{Z} \rightarrow 0$  be a resolution of  $\mathbb{Z}$  by projective  $G$ -modules (for example, the standard resolution). The cohomology groups  $H^n(G, M_H^G(A))$  are computed by taking homomorphisms from this resolution into  $M_H^G(A) = \text{Hom}_{\mathbb{Z}H}(\mathbb{Z}G, A)$ . Since  $\mathbb{Z}G$  is a free  $\mathbb{Z}H$ -module it follows that this  $G$ -module resolution is also a resolution of  $\mathbb{Z}$  by projective  $H$ -modules, hence by taking homomorphisms into  $A$  the same resolution may be used to compute the cohomology groups  $H^n(H, A)$ . To see that these two collections of cohomology groups are isomorphic, we use the natural isomorphism of abelian groups

$$\Phi : \text{Hom}_{\mathbb{Z}G}(P_n, \text{Hom}_{\mathbb{Z}H}(\mathbb{Z}G, A)) \cong \text{Hom}_{\mathbb{Z}H}(P_n, A)$$

given by  $\Phi(f)(p) = f(p)(1)$ , for all  $f \in \text{Hom}_{\mathbb{Z}G}(P_n, \text{Hom}_{\mathbb{Z}H}(\mathbb{Z}G, A))$  and  $p \in P_n$ . The inverse isomorphism is defined by taking  $\Psi(f')(p)$  to be the map from  $\mathbb{Z}G$  to  $A$  that takes  $g \in G$  to the element  $f'(gp)$  in  $A$  for all  $f' \in \text{Hom}_{\mathbb{Z}H}(P_n, A)$  and  $p \in P_n$ , i.e.,  $(\Psi(f')(p))(g) = f'(gp)$ . Note this is well defined because  $P_n$  is a  $G$ -module. (These maps are a special case of an Adjoint Associativity Theorem, cf. Exercise 7.) Since these isomorphisms commute with the cochain maps, they induce isomorphisms on the corresponding cohomology groups, i.e.,  $H^n(G, M_H^G(A)) \cong H^n(H, A)$ , as required.

**Corollary 24.** For any  $G$ -module  $A$  the module  $M_1^G(A)$  is cohomologically trivial for  $G$ , i.e.,  $H^n(G, M_1^G(A)) = 0$  for all  $n \geq 1$ .

*Proof:* This follows immediately from the proposition applied with  $H = 1$  together with the computation of the cohomology of the trivial group in Example 2 preceding Proposition 20.

By the corollary, the fourth example above gives us a short exact sequence of  $G$ -modules

$$0 \longrightarrow A \xrightarrow{\varphi} M \longrightarrow C \longrightarrow 0$$

where  $M = M_1^G(A)$  is cohomologically trivial for  $G$  and where  $C$  is the quotient of  $M_1^G(A)$  by the image of  $A$ . The dimension shifting result in Corollary 22 then becomes:

**Corollary 25.** For any  $G$ -module  $A$  we have  $H^{n+1}(G, A) \cong H^n(G, M_1^G(A)/A)$  for all  $n \geq 1$ .

We next consider several important maps relating various cohomology groups. Some applications of the use of these homomorphisms appear in the following two sections.

In general, suppose we have two groups  $G$  and  $G'$  and that  $A$  is a  $G$ -module and  $A'$  is a  $G'$ -module. If  $\varphi : G' \rightarrow G$  is a group homomorphism then  $A$  becomes a  $G'$ -module by defining  $g' \cdot a = \varphi(g')a$  for  $g' \in G'$  and  $a \in A$ . If now  $\psi : A \rightarrow A'$  is a homomorphism of abelian groups then we consider whether  $\psi$  is a  $G'$ -module homomorphism:

**Definition.** Suppose  $A$  is a  $G$ -module and  $A'$  is a  $G'$ -module. The group homomorphisms  $\varphi : G' \rightarrow G$  and  $\psi : A \rightarrow A'$  are said to be *compatible* if  $\psi$  is a  $G'$ -module homomorphism when  $A$  is made into a  $G'$ -module by means of  $\varphi$ , i.e., if  $\psi(\varphi(g')a) = g'\psi(a)$  for all  $g' \in G'$  and  $a \in A$ .

The point of compatible homomorphisms is that they induce group homomorphisms on associated cohomology groups, as follows.

If  $\varphi : G' \rightarrow G$  and  $\psi : A \rightarrow A'$  are homomorphisms, then  $\varphi$  induces a homomorphism  $\varphi^n : (G')^n \rightarrow G^n$ , and so a homomorphism from  $C^n(G, A)$  to  $C^n(G', A)$  that maps  $f$  to  $f \circ \varphi^n$ . The map  $\psi$  induces a homomorphism from  $C^n(G', A)$  to  $C^n(G', A')$  that maps  $f$  to  $\psi \circ f$ . Taken together we obtain an induced homomorphism

$$\begin{aligned}\lambda_n : C^n(G, A) &\longrightarrow C^n(G', A') \\ f &\longmapsto \psi \circ f \circ \varphi^n.\end{aligned}$$

If in addition  $\varphi$  and  $\psi$  are *compatible* homomorphisms, then it is easy to check that the induced maps  $\lambda_n$  commute with the coboundary operator:

$$\lambda_{n+1} \circ d_n = d_n \circ \lambda_n$$

for all  $n \geq 0$ . It follows that  $\lambda_n$  maps cocycles to cocycles and coboundaries to coboundaries, hence induces a group homomorphism on cohomology:

$$\lambda_n : H^n(G, A) \longrightarrow H^n(G', A')$$

for  $n \geq 0$ .

We consider several instances of such maps:

### Examples

- (1) Suppose  $G = G'$  and  $\varphi$  is the identity map. Then to say that the group homomorphism  $\psi : A \rightarrow A'$  is compatible with  $\varphi$  is simply the statement that  $\psi$  is a  $G$ -module homomorphism. Hence any  $G$ -module homomorphism from  $A$  to  $A'$  induces a group homomorphism

$$H^n(G, A) \longrightarrow H^n(G, A') \quad \text{for } n \geq 0.$$

In particular, if  $0 \rightarrow A \rightarrow B \rightarrow C \rightarrow 0$  is a short exact sequence of  $G$ -modules we obtain induced homomorphisms from  $H^n(G, A)$  to  $H^n(G, B)$  and from  $H^n(G, B)$  to  $H^n(G, C)$  for  $n \geq 0$ . These are simply the homomorphisms in the long exact sequence of Theorem 21.

- (2) (*The Restriction Homomorphism*) If  $A$  is a  $G$ -module, then  $A$  is also an  $H$ -module for any subgroup  $H$  of  $G$ . The inclusion map  $\varphi : H \rightarrow G$  of  $H$  into  $G$  and the identity

map  $\psi : A \rightarrow A$  are compatible homomorphisms. The corresponding induced group homomorphism on cohomology is called the *restriction homomorphism*:

$$\text{Res} : H^n(G, A) \longrightarrow H^n(H, A), \quad n \geq 0.$$

The terminology comes from the fact that the map on cochains from  $C^n(G, A)$  to  $C^n(H, A)$  is simply restricting a map  $f$  from  $G^n$  to  $A$  to the subgroup  $H^n$  of  $G^n$ .

- (3) (*The Inflation Homomorphism*) Suppose  $H$  is a normal subgroup of  $G$  and  $A$  is a  $G$ -module. The elements  $A^H$  of  $A$  that are fixed by  $H$  are naturally a module for the quotient group  $G/H$  under the action defined by  $(gH) \cdot a = g \cdot a$ . It is then immediate that the projection  $\varphi : G \rightarrow G/H$  and the inclusion  $\psi : A^H \rightarrow A$  are compatible homomorphisms. The corresponding induced group homomorphism on cohomology is called the *inflation homomorphism*:

$$\text{Inf} : H^n(G/H, A^H) \longrightarrow H^n(G, A), \quad n \geq 0.$$

- (4) (*The Corestriction Homomorphism*) Suppose that  $H$  is a subgroup of  $G$  of index  $m$  and that  $A$  is a  $G$ -module. Let  $g_1, \dots, g_m$  be representatives for the left cosets of  $H$  in  $G$ . Define a map

$$\psi : M_H^G(A) \longrightarrow A \quad \text{by} \quad f \longmapsto \sum_{i=1}^m g_i \cdot f(g_i^{-1}).$$

Note that if we change any coset representative  $g_i$  by  $g_i h$ , then  $(g_i h) f((g_i h)^{-1}) = g_i h f(h^{-1} g_i^{-1}) = g_i h h^{-1} f(g_i^{-1}) = g_i f(g_i^{-1})$  so the map  $\psi$  is independent of the choice of coset representatives. It is easy to see that  $\psi$  is a  $G$ -module homomorphism (and even that it is surjective), so we obtain a group homomorphism from  $H^n(G, M_H^G(A))$  to  $H^n(G, A)$ , for all  $n \geq 0$ . Since  $A$  is also an  $H$ -module, by Shapiro's Lemma we have an isomorphism  $H^n(G, M_H^G(A)) \cong H^n(H, A)$ . The composition of these two homomorphisms is called the *corestriction homomorphism*:

$$\text{Cor} : H^n(H, A) \longrightarrow H^n(G, A), \quad n \geq 0.$$

This homomorphism can be computed explicitly by composing the isomorphism  $\Psi$  in the proof of Shapiro's Lemma for any resolution of  $\mathbb{Z}$  by projective  $G$ -modules  $P_n$  (note these are  $G$ -modules and not simply  $H$ -modules) with the map  $\psi$ , as follows. For a cocycle  $f \in \text{Hom}_{\mathbb{Z}H}(P_n, A)$  representing a cohomology class  $c \in H^n(H, A)$ , a cocycle  $\text{Cor}(f) \in \text{Hom}_{\mathbb{Z}G}(P_n, A)$  representing  $\text{Cor}(c) \in H^n(G, A)$  is given by

$$\text{Cor}(f)(p) = \sum_{i=1}^m g_i \cdot \Psi(f)(p)(g_i^{-1}) = \sum_{i=1}^m g_i f(g_i^{-1} p),$$

for  $p \in P_n$ . When  $n = 0$  this is particularly simple since we can take  $P_0 = \mathbb{Z}G$ . In this case  $f \in \text{Hom}_{\mathbb{Z}H}(\mathbb{Z}G, A) = M_H^G(A)$  is a cocycle if  $f = a$  is constant for some  $a \in A^H$  and then  $\text{Cor}(f)$  is the constant function with value  $\sum_{i=1}^m g_i \cdot a \in A^G$ :

$$\begin{aligned} \text{Cor} : H^0(H, A) &= A^H \longrightarrow A^G = H^0(G, A) \\ a &\longmapsto \sum_{i=1}^m g_i \cdot a. \end{aligned}$$

The next result establishes a fundamental relation between the restriction and corestriction homomorphisms.

**Proposition 26.** Suppose  $H$  is a subgroup of  $G$  of index  $m$ . Then  $\text{Cor} \circ \text{Res} = m$ , i.e., if  $c$  is a cohomology class in  $H^n(G, A)$  for some  $G$ -module  $A$ , then

$$\text{Cor}(\text{Res}(c)) = mc \in H^n(G, A) \quad \text{for all } n \geq 0.$$

*Proof:* This follows from the explicit formula for corestriction in Example 4 above, as follows. If  $f \in \text{Hom}_{\mathbb{Z}H}(P_n, A)$  were in  $\text{Hom}_{\mathbb{Z}G}(P_n, A)$ , i.e., if  $f$  were also a  $G$ -module homomorphism, then  $g_i f(g_i^{-1} p) = g_i g_i^{-1} f(p) = f(p)$ , for  $1 \leq i \leq m$ . Since restriction is the induced map on cohomology of the natural inclusion of  $\text{Hom}_{\mathbb{Z}G}(P_n, A)$  into  $\text{Hom}_{\mathbb{Z}H}(P_n, A)$ , for such an  $f$  we obtain

$$\begin{aligned} \text{Hom}_{\mathbb{Z}G}(P_n, A) &\xrightarrow{\text{Res}} \text{Hom}_{\mathbb{Z}H}(P_n, A) \xrightarrow{\text{Cor}} \text{Hom}_{\mathbb{Z}G}(P_n, A) \\ f &\longmapsto f \longmapsto mf. \end{aligned}$$

It follows that  $\text{Res} \circ \text{Cor}$  is multiplication by  $m$  on the cohomology groups as well.

**Corollary 27.** Suppose the finite group  $G$  has order  $m$ . Then  $mH^n(G, A) = 0$  for all  $n \geq 1$  and any  $G$ -module  $A$ .

*Proof:* Let  $H = 1$ , so that  $[G : H] = m$ , in Proposition 26. Then for any class  $c \in H^n(G, A)$  we have  $mc = \text{Cor}(\text{Res}(c))$ . Since  $\text{Res}(c) \in H^n(H, A) = H^n(1, A)$ , we have  $\text{Res}(c) = 0$  for all  $n \geq 1$  by the second example preceding Proposition 20. Hence  $mc = 0$  for all  $n \geq 1$ , which is the corollary.

**Corollary 28.** If  $G$  is a finite group then  $H^n(G, A)$  is a torsion abelian group for all  $n \geq 1$  and all  $G$ -modules  $A$ .

*Proof:* This is immediate from the previous corollary.

**Corollary 29.** Suppose  $G$  is a finite group whose order is relatively prime to the exponent of the  $G$ -module  $A$ . Then  $H^n(G, A) = 0$  for all  $n \geq 1$ . In particular, if  $A$  is a finite abelian group with  $(|G|, |A|) = 1$  then  $H^n(G, A) = 0$  for all  $n \geq 1$ .

*Proof:* This follows since the abelian group  $H^n(G, A)$  is annihilated by  $|G|$  by the previous corollary and is annihilated by the exponent of  $A$  by Proposition 20.

Note that the statements in the preceding corollaries are not in general true for  $n = 0$ , since then  $H^0(G, A) = A^G$ , which need not even be torsion.

We mention without proof the following result. Suppose that  $H$  is a normal subgroup of  $G$  and  $A$  is a  $G$ -module. The cohomology groups  $H^n(H, A)$  can be given the structure of  $G/H$ -modules (cf. Exercise 17). It can be shown that there is an exact sequence

$$0 \rightarrow H^1(G/H, A^H) \xrightarrow{\text{Inf}} H^1(G, A) \xrightarrow{\text{Res}} H^1(H, A)^{G/H} \xrightarrow{\text{Tra}} H^2(G/H, A^H) \xrightarrow{\text{Inf}} H^2(G, A)$$

where  $H^1(H, A)^{G/H}$  denotes the fixed points of  $H^1(H, A)$  under the action of  $G/H$  and Tra is the so-called *transgression homomorphism*. This exact sequence relates the

cohomology groups for  $G$  to the cohomology groups for the normal subgroup  $H$  and for the quotient group  $G/H$ . Put another way, the cohomology for  $G$  is related to the cohomology for the factors in the filtration  $1 \leq H \leq G$  for  $G$ . More generally, one could try to relate the cohomology for  $G$  to the cohomology for the factors in a longer filtration for  $G$ . This is the theory of *spectral sequences* and is an important tool in homological algebra.

## Galois Cohomology and Profinite Groups

One important application of group cohomology occurs when the group  $G$  is the Galois group of a field extension  $K/F$ . In this case there are many groups of interest on which  $G$  acts, for example the additive group of  $K$ , the multiplicative group  $K^\times$ , etc. The Galois group  $G = \text{Gal}(K/F)$  is the inverse limit  $\varprojlim \text{Gal}(L/F)$  of the Galois groups of the finite extensions  $L$  of  $F$  contained in  $K$  and is a compact topological group with respect to its Krull topology (i.e., the group operations on  $G$  are continuous with respect to the topology defined by the subgroups  $\text{Gal}(K/L)$  of  $G$  of finite index), cf. Section 14.9. In this situation it is useful (and often essential) to take advantage of the additional topological structure of  $G$ . For example the subfields of  $K$  containing  $F$  correspond bijectively with the *closed* subgroups of  $G = \text{Gal}(K/F)$ , and the example of the composite of the quadratic extensions of  $\mathbb{Q}$  discussed in Section 14.9 shows that in general there are many subgroups of  $G$  that are not closed. Fortunately, the modifications necessary to define the cohomology groups in this context are relatively minor and apply to arbitrary inverse limits of finite groups (the *profinite* groups). If  $G$  is a profinite group then  $G = \varprojlim G/N$  where the inverse limit is taken over the open normal subgroups  $N$  of  $G$  (cf. Exercise 23).

**Definition.** If  $G$  is a profinite group then a *discrete  $G$ -module*  $A$  is a  $G$ -module  $A$  with the discrete topology such that the action of  $G$  on  $A$  is continuous, i.e., the map  $G \times A \rightarrow A$  mapping  $(g, a)$  to  $g \cdot a$  is continuous.

Since  $A$  is given the discrete topology, every subset of  $A$  is open, and in particular every element  $a \in A$  is open. The continuity of the action of  $G$  on  $A$  is then equivalent to the statement that the stabilizer  $G_a$  of  $a$  in  $G$  is an open subgroup of  $G$ , hence is of finite index since  $G$  is compact (cf. Exercise 22). This in turn is equivalent to the statement that  $A = \cup A^H$  where the union is over the open subgroups  $H$  of  $G$ .

Some care must be taken in defining the cohomology groups  $H^n(G, A)$  of a profinite group  $G$  acting on a discrete  $G$ -module  $A$  since there are not enough projectives in this category. For example, when  $G$  is infinite, the free  $G$ -module  $\mathbb{Z}G$  is not a discrete  $G$ -module ( $G$  does not act continuously, cf. Exercise 25). Nevertheless, the explicit description of  $H^n(G, A)$  given in this section (occasionally referred to as the *discrete* cohomology groups) can be easily modified — it is only necessary to require the cochains  $C^n(G, A)$  to be *continuous* maps from  $G^n$  to  $A$ . The definition of the coboundary maps  $d_n$  in equation (18) is precisely the same, as is the definition of the groups of cocycles, coboundaries, and the corresponding cohomology groups. It is customary not to introduce a separate notation for these cohomology groups, but to specify which cohomology is meant in the terminology.

**Definition.** If  $G$  is a profinite group and  $A$  is a discrete  $G$ -module, the cohomology groups  $H^n(G, A)$  computed using continuous cochains are called the *profinite* or *continuous* cohomology groups. When  $G = \text{Gal}(K/F)$  is the Galois group of a field extension  $K/F$  then the *Galois cohomology groups*  $H^n(G, A)$  will always mean the cohomology groups computed using continuous cochains.

When  $G$  is a finite group, every  $G$ -module is a discrete  $G$ -module so the discrete and continuous cohomology groups of  $G$  are the same. When  $G$  is infinite, this need not be the case as shown by the example mentioned previously of the free  $G$ -module  $\mathbb{Z}G$  when  $G$  is an infinite profinite group. All the major results in this section remain valid for the continuous cohomology ‘groups’ when “ $G$ -module” is replaced by “discrete  $G$ -module” and “subgroup” is replaced by “closed subgroup.” For example, the Long Exact Sequence in Group Cohomology remains true as stated, the restriction homomorphism requires the subgroup  $H$  of  $G$  to be a closed subgroup (so that the restriction of a continuous map on  $G^n$  to  $H^n$  remains continuous), Proposition 26 requires  $H$  to be closed, etc.

We can write  $G = \varprojlim(G/N)$  and  $A = \cup A^N$  where  $N$  runs over the open normal subgroups of  $G$  (necessarily of finite index in  $G$  since  $G$  is compact). Then  $A^N$  is a discrete  $G/N$ -module and it is not difficult to show that

$$H^n(G, A) = \varinjlim_N H^n(G/N, A^N) \quad (17.19)$$

where the cohomology groups are continuous cohomology and the direct limit is taken over the collection of all open normal subgroups  $N$  of  $G$  (cf. Exercise 24). Since  $G/N$  is a finite group, the continuous cohomology groups  $H^n(G/N, A^N)$  in this direct limit are just the (discrete) cohomology groups considered earlier in this section. The computation of the continuous cohomology for a profinite group  $G$  can therefore always be reduced to the consideration of finite group cohomology where there is no distinction between the continuous and discrete theories.

## EXERCISES

- Let  $F_n = \mathbb{Z}G \otimes_{\mathbb{Z}} \mathbb{Z}G \otimes_{\mathbb{Z}} \cdots \otimes_{\mathbb{Z}} \mathbb{Z}G$  ( $n+1$  factors) for  $n \geq 0$  with  $G$ -action defined on simple tensors by  $g \cdot (g_0 \otimes g_1 \otimes \cdots \otimes g_n) = (gg_0) \otimes g_1 \otimes \cdots \otimes g_n$ .
  - Prove that  $F_n$  is a free  $\mathbb{Z}G$ -module of rank  $|G|^n$  with  $\mathbb{Z}G$  basis  $1 \otimes g_1 \otimes g_2 \otimes \cdots \otimes g_n$  with  $g_i \in G$ .

Denote the basis element  $1 \otimes g_1 \otimes g_2 \otimes \cdots \otimes g_n$  in (a) by  $(g_1, g_2, \dots, g_n)$  and define the  $G$ -module homomorphisms  $d_n$  for  $n \geq 1$  on these basis elements by  $d_1(g_1) = g_1 - 1$  and

$$\begin{aligned} d_n(g_1, \dots, g_n) &= g_1 \cdot (g_2, \dots, g_n) + \sum_{i=1}^{n-1} (-1)^i (g_1, \dots, g_{i-1}, g_i g_{i+1}, g_{i+2}, \dots, g_n) \\ &\quad + (-1)^n (g_1, \dots, g_{n-1}), \end{aligned}$$

for  $n \geq 2$ . Define the  $\mathbb{Z}$ -module *contracting homomorphisms*

$$\mathbb{Z} \xrightarrow{s_{-1}} F_0 \xrightarrow{s_0} F_1 \xrightarrow{s_1} F_2 \xrightarrow{s_2} \dots$$

on a  $\mathbb{Z}$  basis by  $s_{-1}(1) = 1$  and  $s_n(g_0 \otimes \cdots \otimes g_n) = 1 \otimes g_0 \otimes \cdots \otimes g_n$ .

(b) Prove that

$$\epsilon s_{-1} = 1, \quad d_1 s_0 + s_{-1} \epsilon = 1, \quad d_{n+1} s_n + s_{n-1} d_n = 1, \text{ for all } n \geq 1$$

where the map  $\text{aug} : F_0 \rightarrow \mathbb{Z}$  is the augmentation map  $\text{aug}(\sum_{g \in G} \alpha_g g) = \sum_{g \in G} \alpha_g$ .

(c) Prove that the maps  $s_n$  are a chain homotopy (cf. Exercise 4 in Section 1) between the identity (chain) map and the zero (chain) map from the chain

$$\cdots \longrightarrow F_n \xrightarrow{d_n} F_{n-1} \xrightarrow{d_{n-1}} \cdots \xrightarrow{d_1} F_0 \xrightarrow{\text{aug}} \mathbb{Z} \longrightarrow 0 \quad (*)$$

of  $\mathbb{Z}$ -modules to itself.

(d) Deduce from (c) that all  $\mathbb{Z}$ -module homology groups of  $(*)$  are zero, i.e.,  $(*)$  is an exact sequence of  $\mathbb{Z}$ -modules. Conclude that  $(*)$  is a projective  $G$ -module resolution of  $\mathbb{Z}$ .

2. Let  $P_n$  denote the free  $\mathbb{Z}$ -module with basis  $(g_0, g_1, g_2, \dots, g_n)$  with  $g_i \in G$  and define an action of  $G$  on  $P_n$  by  $g \cdot (g_0, g_1, \dots, g_n) = (gg_0, gg_1, \dots, gg_n)$ . For  $n \geq 1$  define

$$d_n(g_0, g_1, g_2, \dots, g_n) = \sum_{i=0}^n (-1)^i (g_0, \dots, \hat{g}_i, \dots, g_n),$$

where  $(g_0, \dots, \hat{g}_i, \dots, g_n)$  denotes the term  $(g_0, g_1, g_2, \dots, g_n)$  with  $g_i$  deleted.

- (a) Prove that  $P_n$  is a free  $\mathbb{Z}G$ -module with basis  $(1, g_1, g_2, \dots, g_n)$  where  $g_i \in G$ .
- (b) Prove that  $d_{n-1} \circ d_n = 0$  for  $n \geq 1$ . [Show that the term  $(g_0, \dots, \hat{g}_j, \dots, \hat{g}_k, \dots, g_n)$  missing the entries  $g_j$  and  $g_k$  occurs twice in  $d_{n-1} \circ d_n(g_0, g_1, g_2, \dots, g_n)$ , with opposite signs.]
- (c) Prove that  $\varphi : P_n \rightarrow F_n$  defined by

$$\varphi((g_0, g_1, g_2, \dots, g_n)) = g_0 \otimes (g_0^{-1} g_1) \otimes (g_1^{-1} g_2) \cdots \otimes (g_{n-1}^{-1} g_n)$$

is a  $G$ -module isomorphism with inverse  $\psi : P_n \rightarrow F_n$  given by

$$\psi(g_0 \otimes g_1 \otimes \cdots \otimes g_n) = (g_0, g_0 g_1, g_0 g_1 g_2, \dots, g_0 g_1 g_2 \cdots g_n).$$

- (d) Prove that if  $\epsilon(g_0) = 1$  for all  $g_0 \in G$  then

$$\cdots \longrightarrow P_n \xrightarrow{d_n} P_{n-1} \xrightarrow{d_{n-1}} \cdots \xrightarrow{d_1} P_0 \xrightarrow{\epsilon} \mathbb{Z} \longrightarrow 0 \quad (**)$$

is a free  $G$ -module resolution of  $\mathbb{Z}$ . [Show that the isomorphisms in (c) take the  $G$ -module resolutions  $(**)$  and  $(*)$  of the previous exercise into each other.]

3. Let  $F_n$  and  $P_n$  be as in the previous two exercises and let  $A$  be a  $G$ -module.

- (a) Prove that  $\text{Hom}_{\mathbb{Z}G}(F_n, A)$  can be identified with the collection  $C^n(G, A)$  of maps from  $G \times G \times \cdots \times G$  ( $n$  copies) to  $A$  and that under this identification the associated coboundary maps from  $C^n(G, A)$  to  $C^{n+1}(G, A)$  are given by equation (18).
- (b) Prove that  $\text{Hom}_{\mathbb{Z}G}(P_n, A)$  can be identified with the collection of maps  $f$  from  $n+1$  copies  $G \times G \times \cdots \times G$  to  $A$  that satisfy  $f(gg_0, gg_1, \dots, gg_n) = gf(g_0, g_1, \dots, g_n)$ .

The group  $C^n(G, A)$  is sometimes called the group of *inhomogeneous n-cochains of G in A*, and the group in (b) of the previous exercise is called the group of *homogeneous n-cochains of G in A*. The inhomogeneous cochains are easier to describe since there is no restriction on the maps from  $G^n$  to  $A$ , but the coboundary map  $d_n$  on homogeneous cochains is less complicated (and more naturally suggested in topological contexts) than the coboundary map on inhomogeneous cochains. The results of the previous exercises show that the cohomology groups  $H^n(G, A)$  defined using either homogeneous or inhomogeneous cochains are the same and indicate the origin of the coboundary maps  $d_n$  used in the text. Historically,  $H^n(G, A)$  was originally defined using homogeneous cochains.

4. Suppose  $H$  is a normal subgroup of the group  $G$  and  $A$  is a  $G$ -module. For every  $g \in G$  prove that the map  $f(a) = ga$  for  $a \in A^H$  defines an automorphism of the subgroup  $A^H$ .
5. Suppose the  $G$ -module  $A$  decomposes as a direct sum  $A = A_1 \oplus A_2$  of  $G$ -submodules. Prove that for all  $n \geq 0$ ,  $H^n(G, A) \cong H^n(G, A_1) \oplus H^n(G, A_2)$ .
6. Suppose  $0 \rightarrow A \rightarrow M_1 \rightarrow M_2 \rightarrow \cdots \rightarrow M_k \rightarrow C \rightarrow 0$  is an exact sequence of  $G$ -modules where  $M_1, M_2, \dots, M_k$  are cohomologically trivial. Prove that  $H^{n+k}(G, A) \cong H^n(G, C)$  for all  $n \geq 1$ . [Decompose the exact sequence into a succession of short exact sequences and use Corollary 22. For example, if  $0 \rightarrow A \xrightarrow{\alpha} M_1 \xrightarrow{\beta} M_2 \xrightarrow{\gamma} C \rightarrow 0$  is exact, show that  $0 \rightarrow A \rightarrow M_1 \rightarrow B \rightarrow 0$  and  $0 \rightarrow B \rightarrow M_2 \rightarrow C \rightarrow 0$  are both exact, where  $B = M_1 / \text{image } \alpha = M_1 / \ker \beta \cong \text{image } \beta = \ker \gamma$ .]
7. (*Adjoint Associativity*) Let  $R, S$  and  $T$  be rings with 1, let  $P$  be a left  $S$ -module, let  $N$  be a  $(T, S)$ -bimodule, and let  $A$  be a left  $T$ -module. Prove that

$$\Phi : \text{Hom}_S(P, \text{Hom}_T(N, A)) \longrightarrow \text{Hom}_T(N \otimes_S P, A)$$

defined by  $\Phi(f)(n \otimes p) = f(p)(n)$  is an isomorphism of abelian groups. (See also Theorem 43 in Section 10.5).

8. Suppose  $G$  is cyclic of order  $m$  with generator  $\sigma$  and let  $N = 1 + \sigma + \sigma^2 + \cdots + \sigma^{m-1} \in \mathbb{Z}G$ .
  - Prove that the *augmentation* map  $\text{aug}(\sum_{i=0}^{m-1} a_i \sigma^i) = \sum_{i=0}^{m-1} a_i$  is a  $G$ -module homomorphism from  $\mathbb{Z}G$  to  $\mathbb{Z}$ .
  - Prove that multiplication by  $N$  and by  $\sigma - 1$  in  $\mathbb{Z}G$  define a free  $G$ -module resolution of  $\mathbb{Z}$ :  $\dots \xrightarrow{\sigma-1} \mathbb{Z}G \xrightarrow{N} \mathbb{Z}G \xrightarrow{\sigma-1} \dots \xrightarrow{N} \mathbb{Z}G \xrightarrow{\sigma-1} \mathbb{Z}G \xrightarrow{\text{aug}} \mathbb{Z} \rightarrow 0$ .
9. Suppose  $G$  is an infinite cyclic group with generator  $\sigma$ .
  - Prove that multiplication by  $\sigma - 1 \in \mathbb{Z}G$  defines a free  $G$ -module resolution of  $\mathbb{Z}$ :  $0 \rightarrow \mathbb{Z}G \xrightarrow{\sigma-1} \mathbb{Z}G \rightarrow \mathbb{Z} \rightarrow 0$ .
  - Show that  $H^0(G, A) \cong A^G$ , that  $H^1(G, A) \cong A/(\sigma - 1)A$ , and that  $H^n(G, A) = 0$  for all  $n \geq 2$ . Deduce that  $H^1(G, \mathbb{Z}G) \cong \mathbb{Z}$  (so free modules need not be cohomologically trivial).
10. Suppose  $H$  is a subgroup of finite index  $m$  in the group  $G$  and  $A$  is an  $H$ -module. Let  $x_1, \dots, x_m$  be a set of left coset representatives for  $H$  in  $G$ :  $G = x_1H \cup \dots \cup x_mH$ .
  - Prove that  $\mathbb{Z}G = \bigoplus_{i=1}^m x_i \mathbb{Z}H = \bigoplus_{i=1}^m \mathbb{Z}H x_i^{-1}$  and  $\mathbb{Z}G \otimes_{\mathbb{Z}H} A = \bigoplus_{i=1}^m (x_i \otimes A)$  as abelian groups.
  - Let  $f_{i,a}$  be the function from  $\mathbb{Z}G$  to  $A$  defined by

$$f_{i,a}(x) = \begin{cases} ha & \text{if } x = hx_i^{-1} \text{ with } h \in H \\ 0 & \text{otherwise.} \end{cases}$$

- Prove that  $f_{i,a} \in M_H^G(A) = \text{Hom}_{\mathbb{Z}H}(\mathbb{Z}G, A)$ , i.e.,  $f_{i,a}(h'x) = h'f_{i,a}(x)$  for  $h' \in H$ .
- Prove that the map  $\varphi(f) = \sum_{i=1}^m x_i \otimes f(x_i^{-1})$  from  $M_H^G(A)$  to  $\mathbb{Z}G \otimes_{\mathbb{Z}H} A$  is a  $G$ -module homomorphism. [Write  $x_i^{-1}g = h_i x_{i'}^{-1}$  for  $i = 1, \dots, m$  and observe that  $x_i \otimes f(x_i^{-1}g) = x_i \otimes h_i f(x_{i'}^{-1}) = x_i h_i \otimes f(x_{i'}^{-1}) = g x_{i'} \otimes f(x_{i'}^{-1})$ .]
  - Prove that  $\varphi$  gives a  $G$ -module isomorphism  $\varphi : M_H^G(A) \cong \mathbb{Z}G \otimes_{\mathbb{Z}H} A$ . [For the injectivity observe that an  $H$ -module homomorphism is 0 if and only if  $f(x_i^{-1}) = 0$  for  $i = 1, \dots, m$ . For the surjectivity prove that  $\varphi(f_{i,a}) = x_i \otimes a$ .]
  - Prove that the isomorphism  $M_H^G(A) \cong \mathbb{Z}G \otimes_{\mathbb{Z}H} A$  in (d) of the previous exercise need not hold if  $H$  is not of finite index in  $G$ . [If  $G$  is an infinite cyclic group show that Shapiro's Lemma implies  $H^1(G, M_1^G(\mathbb{Z})) = 0$  while  $H^1(G, \mathbb{Z}G) \cong \mathbb{Z}$  by Exercise 9.]

12. If  $H$  is a subgroup of  $G$  and  $A$  is an abelian group let  $M_{G/H}(A)$  denote the abelian group of all maps from the left cosets  $gH$  of  $H$  in  $G$  to  $A$ .
- Prove that  $M_1^G(A) \cong M_1^H(M_{G/H}(A))$  as  $H$ -modules. [If  $\{g_i\}_{i \in \mathcal{I}}$  is a choice of left coset representatives of  $H$  in  $G$  define the correspondence between  $f \in M_1^G(A)$  and  $F : H \rightarrow M_{G/H}(A)$  by  $F(h)(g_i H) = f(g_i h)$ , and check that this is an isomorphism of  $H$ -modules.]
  - A  $G$ -module  $A$  such that  $H^n(H, A) = 0$  for all  $n \geq 1$  and all subgroups  $H$  of  $G$  is called *cohomologically trivial*. Prove that  $M_1^G(A)$  is a cohomologically trivial for any abelian group  $A$ .
  - If  $G$  is finite, prove that  $\mathbb{Z}G \otimes_{\mathbb{Z}} A$  is cohomologically trivial for all abelian groups  $A$ .
13. Suppose  $A$  is a  $G$ -module and  $H$  is a subgroup of  $G$ . Prove that the group homomorphism from  $H^n(G, A)$  to  $H^n(G, M_H^G(A))$  for all  $n \geq 0$  induced from the  $G$ -module homomorphism from  $A$  to  $M_H^G(A)$  in Example 3 following Corollary 22 composed with the isomorphism  $H^n(G, M_H^G(A)) \cong H^n(H, A)$  of Shapiro's Lemma is the restriction homomorphism from  $H^n(G, A)$  to  $H^n(H, A)$ .
14. Suppose  $\varphi : H \rightarrow G$  is the inclusion map of the subgroup  $H$  of  $G$  into  $G$ . If  $A$  is an  $H$ -module and  $M_H^G(A)$  the associated induced  $G$ -module, define the group homomorphism  $\psi : M_H^G(A) \rightarrow A$  by mapping  $f$  to its value at 1:  $\psi(f) = f(1)$ .
- Prove that  $\varphi$  and  $\psi$  are compatible homomorphisms.
  - Prove that the induced group homomorphism from  $H^n(G, M_H^G(A))$  to  $H^n(H, A)$  for  $n \geq 0$  is the isomorphism in Shapiro's Lemma.
15. Suppose  $H$  is a normal subgroup of  $G$  and  $A$  is a  $G$ -module. For fixed  $g \in G$ , let  $\psi(a) = ga$  and  $\varphi(h) = g^{-1}hg$  for  $h \in H$ .
- Prove that  $\varphi$  and  $\psi$  are compatible homomorphisms.
  - For each  $n \geq 0$ , prove that the homomorphism  $\theta_g$  from  $H^n(H, A)$  to  $H^n(H, A)$  induced by the compatible homomorphisms  $\varphi$  and  $\psi$  is an automorphism of  $H^n(H, A)$ . [Observe that both  $\varphi$  and  $\psi$  have inverses.]
  - Show that  $\theta_g$  acting on  $H^0(H, A)$  is the automorphism in Exercise 4.
16. Let  $A$  be a  $G$ -module and for  $g \in G$  let  $\theta_g$  denote the automorphism of  $H^n(G, A)$  defined in the previous exercise.
- Prove that  $\theta_g$  acting on  $H^0(G, A) = A^G$  is the identity map.
  - Prove that  $\theta_g$  acting on  $H^n(G, A)$  is the identity map for  $n \geq 1$ . [By induction on  $n$  and dimension shifting. For  $n = 1$ , use the exact sequence in Corollary 22, together with (a) applied to  $\theta_g$  on  $C^G$ . For  $n \geq 2$  use the isomorphism  $H^{n+1}(G, A) \cong H^n(G, C)$  in Corollary 22.]
17. Suppose that  $H$  is a normal subgroup of  $G$  and  $A$  is a  $G$ -module. For  $n \geq 0$  prove that  $H^n(H, A)$  is a  $G/H$ -module where  $gH$  acts by the automorphism  $\theta_g$  induced by conjugation by  $g$  on  $H$  and the natural action of  $g$  on  $A$  as in Exercise 15. [Use the previous exercise to show this action of a coset is well defined.]
18. Suppose that  $G$  is cyclic of order  $m$ , that  $H$  is a subgroup of  $G$  of index  $d$ , and that  $\mathbb{Z}$  is a trivial  $G$ -module. Use the projective  $G$ -module resolution in Exercise 8 to prove
- that  $\text{Cor} : H^n(H, \mathbb{Z}) \rightarrow H^n(G, \mathbb{Z})$  is multiplication by  $d$  from  $\mathbb{Z}$  to  $\mathbb{Z}$  for  $n = 0$ , from  $\mathbb{Z}/(m/d)\mathbb{Z}$  to  $\mathbb{Z}/m\mathbb{Z}$  if  $n$  is odd, and from 0 to 0 if  $n$  is even,  $n \geq 2$ , and
  - that  $\text{Res} : H^n(G, \mathbb{Z}) \rightarrow H^n(H, \mathbb{Z})$  is the identity map from  $\mathbb{Z}$  to  $\mathbb{Z}$  for  $n = 0$ , and is the natural projection map from  $\mathbb{Z}/m\mathbb{Z}$  to  $\mathbb{Z}/(m/d)\mathbb{Z}$  or from 0 to 0, depending on the parity of  $n \geq 1$ .
19. Let  $p$  be a prime and let  $P$  be a Sylow  $p$ -subgroup of the finite group  $G$ . Show that for

- any  $G$ -module  $A$  and all  $n \geq 0$  the map  $\text{Res} : H^n(G, A) \rightarrow H^n(P, A)$  is injective on the  $p$ -primary component of  $H^1(G, A)$ . Deduce that if  $|A| = p^a$  then the restriction map is injective on  $H^n(G, A)$ . [Use Proposition 26.]
20. Let  $p$  be a prime, let  $G = \langle \sigma \rangle$  be cyclic of order  $p^m$  and let  $W$  be a vector space of dimension  $d > 0$  over  $\mathbb{F}_p$  on which  $\sigma$  acts as a linear transformation. Assume  $W$  has a basis such that the matrix of  $\sigma$  is a  $d \times d$  elementary Jordan block with eigenvalue 1.
- (a) Prove that  $d \leq p^m$ . [Use facts about the minimal polynomial of an elementary Jordan block.]
  - (b) Prove that  $\dim_{\mathbb{F}_p} W^G = 1$ .
  - (c) Prove that  $\dim_{\mathbb{F}_p} (\sigma - 1)W = d - 1$ .
  - (d) If  $N = 1 + \sigma + \cdots + \sigma^{p^m-1}$  is the usual norm element, prove that  $NW$  is of dimension 1 if  $d = p^m$  (respectively, of dimension 0 if  $d < p^m$ ) and that the dimension of  $NW$  is  $d - 1$  (respectively,  $d$ ). [Let  $R$  be the group ring  $\mathbb{F}_p G$ , and show that every nonzero  $R$ -submodule of  $R$  contains  $N$ . Note that  $W$  is a cyclic  $R$ -module and let  $\varphi : R \rightarrow W$  be a surjective homomorphism. Conclude that if  $\varphi$  is not an isomorphism then  $N \in \ker \varphi$ .]
  - (e) Deduce that if  $d = p^m$  then  $H^n(G, W) = 0$ , and if  $d < p^m$  then  $H^n(G, W)$  has order  $p$ , for all  $n \geq 1$  (i.e., these cohomology groups are zero if and only if  $W$  is a free  $\mathbb{F}_p G$ -module).
21. Let  $p$  be a prime, let  $G = \langle \sigma \rangle$  be cyclic of order  $p^m$  and let  $V$  be a  $G$ -module of exponent  $p$ . Let  $V = V_1 \oplus V_2 \oplus \cdots \oplus V_k$  be a decomposition of  $V$  giving the Jordan Canonical Form of  $\sigma$ , where each  $V_i$  is  $\sigma$ -invariant and a matrix of  $\sigma$  on  $V_i$  is an  $d_i \times d_i$  elementary Jordan block with eigenvalue 1,  $d_i \geq 1$  (cf. Section 12.3). Prove that  $|V^G| = p^k$  and  $|H^n(G, V)| = p^s$  where  $s$  is the number of  $V_i$  of dimension less than  $p^m$  over  $\mathbb{F}_p$ , for all  $n \geq 1$ . [Use the preceding exercise and Exercise 5.]
22. Suppose  $G$  is a topological group, i.e., there is a topology on  $G$  such that the maps  $G \times G \rightarrow G$  defined by  $(g_1, g_2) \mapsto g_1 g_2$  and  $G \rightarrow G$  defined by  $g \mapsto g^{-1}$  are continuous.
- (a) If  $H$  is an open subgroup of  $G$  and  $g \in G$ , prove that the cosets  $gH$  and  $Hg$  and the subgroup  $g^{-1}Hg$  are also open.
  - (b) Prove that any open subgroup is also closed. [The complement is the union of cosets as in (a).]
  - (c) Prove that a closed subgroup of finite index is open.
  - (d) If  $G$  is compact prove that every open subgroup  $H$  is of finite index.
23. Suppose  $G$  is a compact topological group. Prove the following are equivalent:
- (i)  $G$  is profinite, i.e.,  $G = \varprojlim G_i$  is the inverse limit of finite groups  $G_i$ .
  - (ii) There exists a family  $\{N_i\}$  ( $i \in \mathcal{I}$ ) of open normal subgroups  $N_i$  in  $G$  such that  $\cap_i N_i = 1$  and in this case  $G \cong \varprojlim(G/N_i)$ .
  - (iii) There exists a family  $\{H_j\}$  ( $j \in \mathcal{J}$ ) of open subgroups  $H_j$  in  $G$  such that  $\cap_j H_j = 1$ .
- [To show (iii) implies (ii), let  $H$  be open in  $G$  and use (d) of the previous exercise to show that  $N = \cap_{g \in G} g^{-1}Hg$  is a finite intersection and conclude that  $N \subseteq H \subseteq G$  and  $N$  is open and normal in  $G$ .]
24. Suppose  $N$  and  $N'$  are open normal subgroups of the profinite group  $G$  and  $N' \subseteq N$ . Prove that the projection homomorphism  $\varphi : G/N' \rightarrow G/N$  and the injection  $\psi : A^N \rightarrow A^{N'}$  are compatible homomorphisms and deduce there is an induced homomorphism from  $H^n(G/N, A^N)$  to  $H^n(G/N', A^{N'})$ .
25. If  $G$  is an infinite profinite group show that  $G$  does not act continuously on  $A = \mathbb{Z}G$ . [Show that the stabilizer of  $a \in A$  is not always of finite index in  $G$ .]

### 17.3 CROSSED HOMOMORPHISMS AND $H^1(G, A)$

In this section we consider in greater detail the cohomology group  $H^1(G, A)$  where  $G$  is a group and  $A$  is a  $G$ -module. From the definition of the coboundary map  $d_1$  in equation (18), if  $f \in C^1(G, A)$  then

$$d_1(f)(g_1, g_2) = g_1 \cdot f(g_2) - f(g_1 g_2) + f(g_1).$$

Thus any function  $f : G \rightarrow A$  is a 1-cocycle if and only if it satisfies the identity

$$f(gh) = f(g) + gf(h) \quad \text{for all } g, h \in G. \quad (17.20)$$

Equivalently, a 1-cocycle is determined by a collection  $\{a_g\}_{g \in G}$  of elements in  $A$  satisfying  $a_{gh} = a_g + ga_h$  for  $g, h \in G$  (and then the 1-cocycle  $f$  is the function sending  $g$  to  $a_g$ ). Note that if 1 denotes the identity of  $G$ , then  $f(1) = f(1^2) = f(1) + 1 \cdot f(1) = 2f(1)$ , so  $f(1) = 0$  is the identity in  $A$ . Thus 1-cocycles are necessarily “normalized” at the identity. It then follows from the cocycle condition that  $f(g^{-1}) = -g^{-1}f(g)$  for all  $g \in G$ .

If  $A$  is a  $G$ -module on which  $G$  acts trivially, then the cocycle condition (20) is simply  $f(gh) = f(g) + f(h)$ , i.e.,  $f$  is simply a *homomorphism* from the multiplicative group  $G$  to the additive group  $A$ . Because of this the functions from  $G$  to  $A$  satisfying (20) are called *crossed homomorphisms*.

A 1-cochain  $f$  is a 1-coboundary if there is some  $a \in A$  such that

$$f(g) = g \cdot a - a \quad \text{for all } g \in G, \quad (17.21)$$

(equivalently,  $a_g = ga - a$  in the notation above). Note that since  $-a \in A$ , the coboundary condition in (21) can also be phrased as  $f(g) = a - g \cdot a$  for some fixed  $a \in A$  and all  $g \in G$ . The 1-coboundaries are called *principal crossed homomorphisms*. With this terminology the cohomology group  $H^1(G, A)$  is the group of crossed homomorphisms modulo the subgroup of principal crossed homomorphisms.

#### Example: (Hilbert's Theorem 90)

Suppose  $G = \text{Gal}(K/F)$  is the Galois group of a finite Galois extension  $K/F$  of fields. Then the multiplicative group  $K^\times$  is a  $G$ -module and  $H^1(G, K^\times) = 0$ . To see this, let  $\{\alpha_\sigma\}$  be the values  $f(\sigma)$  of a 1-cocycle  $f$ , so that  $\alpha_\sigma \in K^\times$  and  $\alpha_{\sigma\tau} = \alpha_\sigma \sigma(\alpha_\tau)$  (the cocycle condition written multiplicatively for the group  $K^\times$ ). By the linear independence of automorphisms (Corollary 8 in Section 14.2), there is an element  $\gamma \in K$  such that

$$\beta = \sum_{\tau \in G} \alpha_\tau \tau(\gamma)$$

is nonzero, i.e.,  $\beta \in K^\times$ . Then for any  $\sigma \in G$  we have

$$\sigma(\beta) = \sum_{\tau \in G} \sigma(\alpha_\tau) \sigma\tau(\gamma) = \alpha_\sigma^{-1} \sum_{\tau \in G} \alpha_{\sigma\tau} \sigma\tau(\gamma) = \alpha_\sigma^{-1} \beta$$

where the second equality comes from the cocycle condition. Hence  $\alpha_\sigma = \beta/\sigma(\beta)$ , which is the multiplicative form of the coboundary condition (21) (for the element  $a = \beta^{-1}$ ). Since every 1-cocycle is a 1-coboundary, we have  $H^1(G, K^\times) = 0$ . The same result holds for infinite Galois extensions by equation (19) in the previous section since  $H^1(G, K^\times)$  is the direct limit of trivial groups.

As a special case, suppose  $K/F$  is a Galois extension with cyclic Galois group  $G$  having generator  $\sigma$ . The cohomology groups for  $G$  were computed explicitly in the previous section, and in particular,  $H^1(G, A) = {}_N A / (\sigma - 1)A$  for any  $G$ -module  $A$  (written additively). Since this group is trivial in the present context, we see that an element  $\alpha$  in  $K$  is in the kernel of the norm map, i.e.,  $N_{K/F}(\alpha) = 1$  if and only if  $\alpha = \sigma(\beta)/\beta$  for some  $\beta \in K$ . (For a direct proof of this result in the cyclic case, cf. Exercise 23 in Section 14.2.)

This famous result for cyclic extensions was first proved by Hilbert and appears as “Theorem 90” in his book (known as the “*Zahlbericht*”) on number theory in 1897. As a result, the more general result  $H^1(G, K^\times) = 0$  is referred to in the literature as “Hilbert’s Theorem 90.” In general, the higher dimensional cohomology groups  $H^n(G, K^\times)$  for  $n \geq 2$  can be nontrivial (cf. Exercise 13).

### Example

Suppose  $G = \text{Gal}(K/F)$  is the Galois group of a finite Galois extension  $K/F$  of fields as in the previous example. Then the additive group  $K$  is also a  $G$ -module and  $H^n(G, K) = 0$  for all  $n \geq 2$ . The proof of this in general uses the fact that there is a *normal basis* for  $K$  over  $F$ , i.e., there is an element  $\alpha \in K$  whose Galois conjugates give a basis for  $K$  as a vector space over  $F$ , or, equivalently,  $K \cong \mathbb{Z}G \otimes_{\mathbb{Z}} F$  as  $G$ -modules. The latter isomorphism shows that  $K$  is induced as a  $G$ -module, and then  $H^n(G, K) = 0$  follows from Corollary 24 in Section 2. For a direct proof in the case where  $G$  is cyclic, cf. Exercise 26 in Section 14.2.

If  $G$  acts trivially on  $A$ , then  $g \cdot a - a = 0$ , so 0 is the only principal crossed homomorphism, i.e.,  $B^1(G, A) = 0$ . This proves the following result:

**Proposition 30.** If  $A$  is a  $G$ -module on which  $G$  acts trivially then  $H^1(G, A) = \text{Hom}(G, A)$ , the group of all group homomorphisms from  $G$  to  $A$ .

If  $G$  is a profinite group, then the same result holds for the continuous cohomology group  $H^1(G, A)$  provided one takes the group of continuous homomorphisms from  $G$  into  $A$ .

### Examples

- (1) If  $G$  acts trivially on  $A$  then  $H^1(G, A) = H^1(G/[G, G], A)$  since any group homomorphism from  $G$  to the abelian group  $A$  factors through the commutator subgroup  $[G, G]$  (cf. Proposition 7(5) in Section 5.4), so computing  $H^1$  for trivial  $G$ -action reduces to computing  $H^1$  for some abelian group.
- (2) If  $G$  is a finite group acting trivially on  $\mathbb{Z}$ , then  $H^1(G, \mathbb{Z}) = 0$  because  $\mathbb{Z}$  has no nonzero elements of finite order so there is no nonzero group homomorphism from  $G$  to  $\mathbb{Z}$ .
- (3) If  $A$  is cyclic of prime order  $p$  and  $G$  is a  $p$ -group then  $G$  must act trivially on  $A$  (since the automorphism group of  $A$  has order  $p - 1$ ), so in this case one always has  $H^1(G, A) = \text{Hom}(G, A)$ .
- (4) If  $G$  is a finite group that acts trivially on  $\mathbb{Q}/\mathbb{Z}$  then  $H^1(G, \mathbb{Q}/\mathbb{Z}) = \text{Hom}(G, \mathbb{Q}/\mathbb{Z}) = \hat{G}$  is the *dual group* of  $G$  (cf. Exercise 14 in Section 5.2.). Since  $\mathbb{Q}/\mathbb{Z}$  is abelian, any homomorphism of  $G$  into  $\mathbb{Q}/\mathbb{Z}$  factors through the commutator quotient  $G^{\text{ab}} = G/[G, G]$  of  $G$ , so  $\text{Hom}(G, \mathbb{Q}/\mathbb{Z}) = \text{Hom}(G^{\text{ab}}, \mathbb{Q}/\mathbb{Z})$ . It follows that  $\text{Hom}(G, \mathbb{Q}/\mathbb{Z}) \cong \hat{G}^{\text{ab}}$  (which by cf. Exercise 14 again is noncanonically isomorphic to  $G^{\text{ab}}$ ).

If  $0 \rightarrow A \rightarrow B \rightarrow C \rightarrow 0$  is a short exact sequence of  $G$ -modules then the long exact sequence in group cohomology in Theorem 21 of the previous section begins with terms

$$0 \longrightarrow A^G \longrightarrow B^G \longrightarrow C^G \xrightarrow{\delta_0} H^1(G, A) \longrightarrow \dots.$$

The connecting homomorphism  $\delta_0$  is given explicitly as follows: if  $c \in C^G$  then there is an element  $b \in B$  mapping to  $c$  and then  $\delta_0(c)$  is the class in  $H^1(G, A)$  of the 1-cocycle given by

$$\begin{aligned}\delta_0(c) : G &\longrightarrow A \\ g &\longmapsto g \cdot b - b.\end{aligned}$$

Note that  $g \cdot b - b$  is (the image in  $B$  of) an element of  $A$  for all  $g \in G$  since  $c \in C^G$ . To verify directly that  $f = \delta_0(c)$  satisfies the cocycle condition in (20), we compute

$$f(gh) = gh \cdot b - b = (g \cdot b - b) + g \cdot (h \cdot b - b) = f(g) + gf(h).$$

From the explicit expression  $f = g \cdot b - b$  it is also clear that  $\delta_0(c) \in H^1(G, A)$  maps to 0 in the next term  $H^1(G, B)$  of the long exact sequence above since  $f$  is the coboundary for the element  $b \in B$ .

### Example: (Kummer Theory)

Suppose that  $F$  is a field of characteristic 0 containing the group  $\mu_n$  of all  $n^{\text{th}}$  roots of unity for some  $n \geq 1$ . Let  $K$  be an algebraic closure of  $F$  and let  $G = \text{Gal}(K/F)$ . The group  $G$  acts trivially on  $\mu_n$  since  $\mu_n \subset F$  by assumption, i.e.,  $\mu_n \cong \mathbb{Z}/n\mathbb{Z}$  as  $G$ -modules. Hence the Galois cohomology group  $H^1(G, \mu_n)$  is the group  $\text{Hom}_c(G, \mathbb{Z}/n\mathbb{Z})$  of continuous homomorphisms of  $G$  into  $\mathbb{Z}/n\mathbb{Z}$ . If  $\chi$  is such a continuous homomorphism, then  $\ker \chi \subseteq G$  is a closed normal subgroup of  $G$ , hence corresponds by Galois theory to a Galois extension  $L_\chi/F$ . Then  $\text{Gal}(L_\chi/F) \cong \text{image } \chi$ , so  $L_\chi$  is a cyclic extension of  $F$  of degree dividing  $n$ . Conversely, every such cyclic extension of  $F$  defines an element in  $\text{Hom}_c(G, \mathbb{Z}/n\mathbb{Z})$ , so there is a bijection between the elements of the Galois cohomology group  $H^1(G, \mu_n)$  and the cyclic extensions of  $F$  of degree dividing  $n$ .

The homomorphism of raising to the  $n^{\text{th}}$  power is surjective on  $K^\times$  (since we can always extract  $n^{\text{th}}$  roots in  $K$ ) and has kernel  $\mu_n$ . Hence the sequence

$$1 \longrightarrow \mu_n \longrightarrow K^\times \xrightarrow{n} K^\times \longrightarrow 1$$

is an exact sequence of discrete  $G$ -modules. The associated long exact sequence in Galois cohomology gives

$$1 \longrightarrow \mu_n^G \longrightarrow (K^\times)^G \xrightarrow{n} (K^\times)^G \longrightarrow H^1(G, \mu_n) \longrightarrow H^1(G, K^\times) \longrightarrow \dots.$$

We have  $\mu_n^G = \mu_n$  and  $(K^\times)^G = F^\times$  by Galois theory, and  $H^1(G, K^\times) = 0$  by Hilbert's Theorem 90, so this exact sequence becomes

$$1 \longrightarrow \mu_n \longrightarrow F^\times \xrightarrow{n} F^\times \longrightarrow H^1(G, \mu_n) \longrightarrow 0,$$

which in turn is equivalent to the isomorphism

$$H^1(G, \mu_n) \cong F^\times / F^{\times n}$$

where  $F^{\times n}$  denotes the group of  $n^{\text{th}}$  powers of elements of  $F^\times$ . This isomorphism is made explicit using the explicit form for the connecting homomorphism given above: for every  $\alpha \in F^\times$  and  $\sigma \in G$ , the element  $\sqrt[n]{\alpha}$  in  $K^\times$  maps to  $\alpha$  in the exact sequence and

$$\chi(\sigma) = \frac{\sigma(\sqrt[n]{\alpha})}{\sqrt[n]{\alpha}}$$

defines an element in  $H^1(G, \mu_n)$  (cf. Exercise 11). The kernel of this homomorphism  $\chi$  is the field  $F(\sqrt[n]{\alpha})$ . By the results of the previous paragraph, when  $F$  contains the  $n^{\text{th}}$  roots of unity an extension  $L/F$  is Galois with cyclic Galois group of order dividing  $n$  if and only if  $L = F(\sqrt[n]{\alpha})$  for some  $\alpha \in F^\times$ . Furthermore, the class of  $\alpha$  in  $F^\times/F^{\times n}$  is unique, i.e.,  $\alpha$  is unique up to an  $n^{\text{th}}$  power of an element in  $F$ . Such an extension is called a *Kummer extension*, cf. Section 14.7 and Exercise 12.

If the characteristic of  $F$  is a prime  $p$ , the same argument applies when  $n$  is not divisible by  $p$ , replacing the algebraic closure of  $F$  with the separable closure of  $F$  (the largest separable algebraic extension of  $F$ ).

### Example: (The Transfer Homomorphism)

Suppose  $G$  is a finite group and  $H$  is a subgroup. The corestriction defines a homomorphism from  $H^1(H, \mathbb{Q}/\mathbb{Z})$  to  $H^1(G, \mathbb{Q}/\mathbb{Z})$ , which by Example 4 above gives a homomorphism from  $H^{\text{ab}}$  to  $G^{\text{ab}}$ . This gives a homomorphism

$$\text{Ver} : G^{\text{ab}} \longrightarrow H^{\text{ab}}$$

called the *transfer* (or *Verlagerungen*) homomorphism (cf. Exercise 14). To make this homomorphism explicit, consider the exact sequence

$$0 \longrightarrow \mathbb{Q}/\mathbb{Z} \longrightarrow M_1^G(\mathbb{Q}/\mathbb{Z}) \longrightarrow C \longrightarrow 0 \tag{17.22}$$

defined by the homomorphism mapping  $a \in \mathbb{Q}/\mathbb{Z}$  to  $f_a \in M_1^G(\mathbb{Q}/\mathbb{Z})$  in Example 4 preceding Proposition 23 in the previous section (so  $f_a(g) = g \cdot a$  for  $g \in G$ ). This is a short exact sequence of  $G$ -modules and hence also of  $H$ -modules. The first portions of the associated long exact sequences for the cohomology with respect to  $H$  and then  $G$  give the rows in the commutative diagram

$$\begin{array}{ccccccc} \cdots & \longrightarrow & C^H & \xrightarrow{\delta_0} & H^1(H, \mathbb{Q}/\mathbb{Z}) & \longrightarrow & 0 \\ & & \downarrow \text{Cor} & & \downarrow \text{Cor} & & \\ \cdots & \longrightarrow & C^G & \xrightarrow{\delta_0} & H^1(G, \mathbb{Q}/\mathbb{Z}) & \longrightarrow & 0 \end{array}$$

since  $H^1(H, M_1^G(\mathbb{Q}/\mathbb{Z})) = H^1(G, M_1^G(\mathbb{Q}/\mathbb{Z})) = 0$  (cf. Exercise 12 in Section 2). Let  $\chi \in H^1(H, \mathbb{Q}/\mathbb{Z})$  and suppose that  $c \in C^H$  is an element mapping to  $\chi$  by the surjective connecting homomorphism  $\delta_0$  in the first row of the diagram above. By the commutativity,  $\chi' = \text{Cor}(\chi)$  is the image under the connecting homomorphism  $\delta_0$  of  $c' = \text{Cor}(c) \in C^G$  in the second row of the diagram. By our explicit formula for the coboundary map  $\delta_0$ , if  $F \in M_1^G(\mathbb{Q}/\mathbb{Z})$  is any element mapping to  $c'$  in (22) then  $g \cdot F - F = f_{a'}^g$  for a unique  $a' \in \mathbb{Q}/\mathbb{Z}$ , and we have  $\chi'(g) = \delta_0(c')(g) = a'$  for  $g \in G$ . Since  $f_{a'}(x) = x \cdot a' = a'$  for any  $x \in G$  because  $G$  acts trivially on  $\mathbb{Q}/\mathbb{Z}$ , the function  $g \cdot F - F$  in fact has the constant value  $a'$ , and so can be evaluated at any  $x \in G$  to determine the value of  $\chi'(g)$ .

Since  $c' = \sum_{i=1}^m g_i \cdot c \in C^G$  where  $g_1, \dots, g_m$  are representatives of the left cosets of  $H$  in  $G$  (cf. Example 4 preceding Proposition 26), such an element  $F$  is given by

$$F = \sum_{i=1}^m g_i \cdot f,$$

where  $f \in M_1^G(\mathbb{Q}/\mathbb{Z})$  is any element mapping to  $c$  in (22). This  $f$  can be used to compute the explicit coboundary of  $c$  as before:  $h \cdot f - f = f_a$  for a unique  $a \in \mathbb{Q}/\mathbb{Z}$  and  $\chi(h) = a$  for  $h \in H$ . As before, the function  $h \cdot f - f = f_a$  has the constant value  $a$  and so can be evaluated at any element  $x$  of  $G$  to determine the value of  $\chi(h)$ .

Computing  $g \cdot F - F$  on the element  $1 \in G$  it follows that

$$\chi'(g) = \sum_{i=1}^m f(gg_i) - \sum_{i=1}^m f(g_i).$$

For  $i = 1, \dots, m$ , write

$$gg_i = g_j h(g, g_i) \quad \text{with } h(g, g_i) \in H, \quad (17.23)$$

noting that the resulting set of  $g_j$  is some permutation of  $\{g_1, \dots, g_m\}$ . Then

$$\sum_{i=1}^m f(gg_i) - \sum_{i=1}^m f(g_i) = \sum_{i=1}^m [f(g_j h(g, g_i)) - f(g_j)] = \sum_{i=1}^m \chi(h(g, g_i))$$

since as noted above,  $\chi(h) = f(xh) - f(x)$  for any  $x \in G$ . Hence

$$\chi'(g) = \chi\left(\prod_{i=1}^m h(g, g_i)\right)$$

and so the transfer homomorphism is given by the formula

$$\text{Ver}(g) = \prod_{i=1}^m h(g, g_i) \quad (17.24)$$

with the elements  $h(g, g_i) \in H$  defined by equation (23). Note that this proves in particular that the map defined in (24) is a homomorphism from  $G^{\text{ab}}$  to  $H^{\text{ab}}$  that is independent of the choice of representatives  $g_i$  for  $H$  in  $G$  in (23). Proving that this map is a homomorphism directly is not completely trivial. The same formula also defines the transfer homomorphism when  $G$  is infinite and  $H$  is a subgroup of finite index in  $G$ .

As an example of the transfer, suppose  $H = n\mathbb{Z}$  and  $G = \mathbb{Z}$  and choose  $0, 1, 2, \dots, n-1$  as coset representatives for  $H$  in  $G$ . If  $g = 1$ , then all the elements  $h(g, g_i)$  are 0 for  $i = 1, 2, \dots, n-1$  and  $h(1, n-1) = n$ . Hence the transfer map from  $\mathbb{Z}$  to  $n\mathbb{Z}$  maps 1 to  $n$ , so is simply multiplication by the index. Similarly, the transfer map from any cyclic group  $G$  to a subgroup  $H$  of index  $n$  is the  $n^{\text{th}}$  power map. See also Exercise 8.

For the cyclic group  $\mathbb{F}_p^\times$  for an odd prime  $p$  and subgroup  $\{\pm 1\}$ , it follows that the transfer map is the homomorphism  $\text{Ver} : \mathbb{F}_p^\times \rightarrow \{\pm 1\}$  given by

$$\text{Ver}(a) = a^{(p-1)/2} = \left(\frac{a}{p}\right) = \begin{cases} +1 & \text{if } a \text{ is a square} \\ -1 & \text{if } a \text{ is not a square} \end{cases}$$

(the symbol  $\left(\frac{a}{p}\right)$  is called the *Legendre symbol* or the *quadratic residue symbol*). If instead we take the elements  $1, 2, \dots, (p-1)/2$  as coset representatives for  $\{\pm 1\}$  in  $\mathbb{F}_p^\times$  we see that

$$\left(\frac{a}{p}\right) = (-1)^{m(a)}$$

where  $m(a)$  is the number of elements among  $a, 2a, \dots, (p-1)a/2$  whose least positive remainder modulo  $p$  is greater than  $(p-1)/2$  (in which case the element differs by  $-1$  from one of our chosen coset representatives and contributes one factor of  $-1$  to the product in (24)). This result is known as *Gauss' Lemma* in elementary number theory and can be used to prove Gauss' celebrated Quadratic Reciprocity Law (cf. also Exercise 15).

Next we give two important interpretations of  $H^1(G, A)$  in terms of semidirect products. If  $A$  is a  $G$ -module, let  $E$  be the semidirect product  $E = A \rtimes G$ , where  $A$  is normal in  $E$  and the action of  $G$  (viewed as a subgroup of  $E$ ) on  $A$  by conjugation is the same as its  $G$ -module action:  $gag^{-1} = g \cdot a$ . In the notation of Section 5.5,  $E = A \rtimes_{\varphi} G$ , where  $\varphi$  is the homomorphism of  $G$  into  $\text{Aut}(A)$  given by the  $G$ -module action. In particular,  $E$  will be the direct product of  $A$  and  $G$  if and only if  $G$  acts trivially on  $A$ . As in Section 5.5, we shall write the elements of  $E$  as  $(a, g)$  where  $a \in A$  and  $g \in G$ , with group operation

$$(a_1, g_1)(a_2, g_2) = (a_1 + g_1 \cdot a_2, g_1 g_2).$$

Note that  $A$  is written additively, while  $G$  and  $E$  are written multiplicatively.

**Definition.** Let  $X$  be any group and let  $Y$  be a normal subgroup of  $X$ . The *stability group* of the series  $1 \trianglelefteq Y \trianglelefteq X$  is the group of all automorphisms of  $X$  that map  $Y$  to itself and act as the identity on both of the factors  $Y$  and  $X/Y$ , i.e.,

$$\begin{aligned} \text{Stab}(1 \trianglelefteq Y \trianglelefteq X) = \{ \sigma \in \text{Aut}(X) \mid & \sigma(y) = y \text{ for all } y \in Y, \\ & \text{and } \sigma(x) \equiv x \pmod{Y} \text{ for all } x \in X \}. \end{aligned}$$

In the special case where  $Y$  is an *abelian* normal subgroup of  $X$ , conjugation by elements of  $Y$  induce (inner) automorphisms of  $X$  that stabilize the series  $1 \trianglelefteq Y \trianglelefteq X$ , and in this case  $Y/C_Y(X)$  is isomorphic to a subgroup of  $\text{Stab}(1 \trianglelefteq Y \trianglelefteq X)$  (where  $C_Y(X)$  is the elements of  $Y$  in the center of  $X$ ).

**Proposition 31.** Let  $A$  be a  $G$ -module and let  $E$  be the semidirect product  $A \rtimes G$ . For each cocycle  $f \in Z^1(G, A)$  define  $\sigma_f : E \rightarrow E$  by

$$\sigma_f((a, g)) = (a + f(g), g).$$

Then the map  $f \rightarrow \sigma_f$  is a group isomorphism from  $Z^1(G, A)$  onto  $\text{Stab}(1 \trianglelefteq A \trianglelefteq E)$ . Under this isomorphism the subgroup  $B^1(G, A)$  of coboundaries maps onto the subgroup  $A/C_A(E)$  of the stability group.

*Proof:* It is an exercise to see that the cocycle condition implies  $\sigma_f$  is an automorphism of  $E$  that stabilizes the chain  $1 \trianglelefteq A \trianglelefteq E$ . Likewise one checks directly that  $\sigma_{f_1+f_2} = \sigma_{f_1} \circ \sigma_{f_2}$ , so the map  $f \mapsto \sigma_f$  is a group homomorphism. By definition of  $\sigma_f$  this map is injective. Conversely, let  $\sigma \in \text{Stab}(1 \trianglelefteq A \trianglelefteq E)$ . Since  $\sigma$  acts trivially on  $E/A$ , each element  $(0, g)$  in this semidirect product maps under  $\sigma$  to another element  $(a, g)$  in the same coset of  $A$ ; define  $f_\sigma : G \rightarrow A$  by letting  $f_\sigma(g) = a$ . If we identify  $A$  with the elements of the form  $(a, 1)$  in  $E$ , then the group operation in  $E$  shows that

$$f_\sigma(g) = \sigma((0, g))(0, g)^{-1}.$$

Because  $\sigma$  is a stability automorphism of  $E$ , it is easy to check that  $f_\sigma$  satisfies the cocycle condition. It follows immediately from the definitions that  $f_{\sigma_f} = f$ , so the map  $f \mapsto \sigma_f$  is an isomorphism.

Now  $f$  is a coboundary if and only if there is some  $x \in A$  such that  $f(g) = x - g \cdot x$  for all  $g \in G$ . Thus  $f$  is a coboundary if and only if  $\sigma_f((a, g)) = (a + x - g \cdot x, g)$ . But conjugation in  $E$  by the element  $(x, 1)$  maps  $(a, g)$  to the same element  $(a + x - g \cdot x, g)$ , so the automorphism  $\sigma_f$  is conjugation by  $(x, 1)$ . This proves the remaining assertion of the proposition.

**Corollary 32.** In the notation of Proposition 31 let  $\varphi_a$  denote the automorphism of  $E$  given by conjugation by  $a$  for any  $a \in A$ . Then the cocycles  $f_1$  and  $f_2$  are in the same cohomology class in  $H^1(G, A)$  if and only if  $\sigma_{f_1} = \varphi_a \circ \sigma_{f_2}$ , for some  $a \in A$ .

The proposition and corollary show that 1-cocycles may be computed by finding automorphisms of  $E$  that stabilize the series  $1 \trianglelefteq A \trianglelefteq E$ , and vice versa. The first cohomology group is then given by taking these automorphisms modulo inner automorphisms, i.e., is the group of “outer stability automorphisms” of this series.

### Example

Let  $G = Z_2$  act by inversion on  $A = \mathbb{Z}/4\mathbb{Z}$ . The corresponding semidirect product  $E = A \rtimes G$  is the dihedral group of order 8, which has automorphism group isomorphic to  $D_8$ ; viewing  $E$  as a normal (index 2) subgroup of  $D_{16}$ , conjugation in the latter group restricted to  $E$  exhibits 8 distinct automorphisms of  $E$  (cf. Proposition 17 in Section 4.4). The subgroup  $A$  of  $E$  is characteristic in  $E$ , hence every automorphism of  $E$  sends  $A$  to itself, and therefore also acts on  $E/A$  (necessarily trivially since  $|E/A| = 2$ ). Half the automorphisms of  $E$  invert  $A$  and half centralize  $A$ ; in fact, the cyclic subgroup of order 8 in  $D_{16}$  (which contains  $A$ ) maps to a cyclic group of order 4 of automorphisms centralizing  $A$ . Thus  $\text{Stab}(1 \trianglelefteq A \trianglelefteq E) \cong \mathbb{Z}_4 \cong Z^1(G, A)$ . Since the center of  $E$  is a subgroup of  $A$  of order 2,  $|A/Z(E)| = 2 = |B^1(G, A)|$ . This proves  $|H^1(G, A)| = 2$ .

In the semidirect product  $E$  the subgroup  $G$  is a complement to  $A$ , i.e.,  $E = AG$  and  $A \cap G = 1$ ; moreover, every  $E$ -conjugate of  $G$  is also a complement to  $A$ . But  $A$  may have complements in  $E$  that are not conjugate to  $G$  in  $E$ . Our second interpretation of  $H^1(G, A)$  shows that this cohomology group characterizes the  $E$ -conjugacy classes of complements of  $A$  in  $E$ .

**Proposition 33.** Let  $A$  be a  $G$ -module and let  $E$  be the semidirect product  $A \rtimes G$ . For each 1-cocycle  $f$  let

$$G_f = \{(f(g), g) \mid g \in G\}.$$

Then  $G_f$  is a subgroup complement to  $A$  in  $E$ . The map  $f \mapsto G_f$  is a bijection from  $Z^1(G, A)$  to the set of complements to  $A$  in  $E$ . Two complements are conjugate in  $E$  if and only if their corresponding 1-cocycles are in the same cohomology class in  $H^1(G, A)$ , so there is a bijection between  $H^1(G, A)$  and the set of  $E$ -conjugacy classes of complements to  $A$ .

*Proof:* By the cocycle condition,

$$(f(g), g)(f(h), h) = (f(g) + gf(h)g^{-1}, gh) = (f(g) + g \cdot f(h), gh) = (f(gh), gh),$$

and it follows that  $G_f$  is closed under the group operation in  $E$ . As observed earlier, each cocycle necessarily has  $f(1) = 0$ , so  $G_f$  contains the identity  $(0, 1)$  of  $E$ . The inverse to  $(f(g), g)$  in  $E$  is  $(f(g^{-1}), g^{-1})$ , so  $G_f$  is closed under inverses. This proves  $G_f$  is a subgroup of  $E$ . Since the distinct elements of  $G_f$  represent the distinct cosets of  $A$  in  $E$ ,  $G_f$  is a complement to  $A$  in  $E$ . Distinct cocycles give different coset representatives, hence they determine different complements.

Conversely, if  $C$  is any complement to  $A$  in  $G$ , then  $C$  contains a unique coset representative  $a_g g$  of  $Ag$  for each  $g \in G$ . Since  $C$  is closed under the group operation the element  $(a_g g)(a_h h) = (a_g g a_h h^{-1})gh$  represents the coset  $Agh$ , and so  $a_{gh}$  is  $a_g g a_h h^{-1} = a_g(g \cdot a_h)$  (written additively in  $A$  this becomes  $a_{gh} = a_g + (g \cdot a_h)$ ). This shows that the map  $f : G \rightarrow A$  given by  $f(g) = a_g$  is a cocycle, and so  $C = G_f$ . Hence there is a bijection between 1-cocycles and complements to  $A$  in  $E$ .

Since  $\text{Stab}(1 \trianglelefteq A \trianglelefteq E)$  normalizes  $A$  it permutes the complements to  $A$  in  $E$ . In the notation of Proposition 31, for 1-cocycles  $f_1$  and  $f_2$  it follows immediately from the definition that  $\sigma_{f_1}(G_{f_2}) = G_{f_1+f_2}$ . This shows that the permutation action of  $\text{Stab}(1 \trianglelefteq A \trianglelefteq E)$  on the set of complements to  $A$  in  $E$  is the (left) regular representation of this group. Furthermore, if  $a \in A$  and  $\varphi_a$  is the stability automorphism conjugation by  $a$ , then

$$aG_f a^{-1} = \varphi_a(G_f) = G_{f+\beta_a} \quad (17.25)$$

where  $\beta_a$  is the 1-coboundary  $\beta_a : g \mapsto a - g \cdot a$ . Since  $G_f$  is a complement to  $A$ , any  $e \in E$  may be written as  $ag$  for some  $a \in A$  and  $g \in G_f$ . Then  $eG_f e^{-1} = aG_f a^{-1}$ , i.e., the  $E$ -conjugates of  $G_f$  are the just the  $A$ -conjugates of  $G_f$ . Now the complements  $G_{f_1}$  and  $G_{f_2}$  are conjugate in  $E$  if and only if  $G_{f_2} = aG_{f_1}a^{-1} = G_{f_1+\beta_a}$  for some  $a \in A$  by (25). This shows two complements are conjugate in  $E$  if and only if their corresponding cocycles differ by a coboundary, i.e., represent the same cohomology class in  $H^1(G, A)$ , which completes the proof.

**Corollary 34.** Under the notation of Proposition 33, all complements to  $A$  are conjugate in  $E$  if and only if  $H^1(G, A) = 0$ .

**Corollary 35.** If  $A$  is a finite abelian group whose order is relatively prime to  $|G|$  then all complements to  $A$  in any semidirect product  $E = A \rtimes G$  are conjugate in  $E$ .

## Examples

- (1) Let  $A = \langle a \rangle$  and  $G = \langle g \rangle$  both be cyclic of order 2. The group  $G$  must act trivially on  $A$ , hence  $A \rtimes G = A \times G$  is a Klein 4-group. Here  $A \rtimes G$  is abelian, so every subgroup is conjugate only to itself, and since  $H^1(G, A) = \text{Hom}(Z_2, \mathbb{Z}/2\mathbb{Z})$  has order 2, there are precisely two complements to  $A$  in  $E$ , namely  $\langle g \rangle$  and  $\langle ag \rangle$ .
- (2) If  $A = \langle a \rangle$  is cyclic of order 2 and  $G = \langle x \rangle \times \langle y \rangle$  is a Klein 4-group, then as before  $G$  must act trivially on  $A$ , so  $H^1(G, A) = \text{Hom}(Z_2 \times Z_2, \mathbb{Z}/2\mathbb{Z})$  has order 4. The four complements to  $A$  in  $A \rtimes G$  are  $G$ ,  $\langle ax, y \rangle$ ,  $\langle x, ay \rangle$  and  $\langle ax, ay \rangle$ .
- (3) Proposition 33 can also be used to compute  $H^1(G, A)$ . Let  $A = \langle r \rangle$  be cyclic of order 4 and let  $G = \langle s \rangle$  be cyclic of order 2 acting on  $A$  by inversion:  $srs^{-1} = r^{-1}$  as in the Example following Corollary 32. Then  $A \rtimes G$  is the dihedral group  $D_8$  of order 8. The subgroup  $A$  has four complements in  $D_8$ , namely the groups generated

by each of the four elements of order 2 not in  $A$ :  $\langle s \rangle$ ,  $\langle r^2s \rangle$ ,  $\langle rs \rangle$  and  $\langle r^3s \rangle$ . The former pair and the latter pair are conjugate in  $D_8$  (in both cases via  $r$ ), but  $\langle s \rangle$  is not conjugate to  $\langle rs \rangle$ . Thus  $A$  has 2 conjugacy classes of complements in  $A \rtimes G$  and hence  $H^1(Z_2, \mathbb{Z}/4\mathbb{Z})$  has order 2. This also follows from the computation of the cohomology of cyclic groups in Section 2.

## EXERCISES

1. Let  $G$  be the cyclic group of order 2 and let  $A$  be a  $G$ -module. Compute the isomorphism types of  $Z^1(G, A)$ ,  $B^1(G, A)$  and  $H^1(G, A)$  for each of the following:
  - (a)  $A = \mathbb{Z}/4\mathbb{Z}$  (trivial action),
  - (b)  $A = \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$  (trivial action),
  - (c)  $A = \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$  (any nontrivial action).
2. Let  $p$  be a prime and let  $P$  be a  $p$ -group.
  - (a) Show that  $H^1(P, \mathbb{F}_p) \cong P/\Phi(P)$ , where  $\Phi(P)$  is the Frattini subgroup of  $P$  (cf. the exercises in Section 6.1).
  - (b) Deduce that the dimension of  $H^1(P, \mathbb{F}_p)$  as a vector space over  $\mathbb{F}_p$  equals the minimum number of generators of  $P$ . [Use Exercise 26(c), Section 6.1.]
3. If  $G$  is the cyclic group of order 2 acting by inversion on  $\mathbb{Z}$  show that  $|H^1(G, \mathbb{Z})| = 2$ . [Show that in  $E = \mathbb{Z} \rtimes G$  every element of  $E - \mathbb{Z}$  has order 2, and there are two conjugacy classes in this coset.]
4. Let  $A$  be the Klein 4-group and let  $G = \text{Aut}(A) \cong S_3$  act on  $A$  in the natural fashion. Prove that  $H^1(G, A) = 0$ . [Show that in the semidirect product  $E = A \rtimes G$ ,  $G$  is the normalizer of a Sylow 3-subgroup of  $E$ . Apply Sylow's Theorem to show all complements to  $A$  in  $E$  are conjugate.]
5. Let  $G$  be the cyclic group of order 2 acting on an elementary abelian 2-group  $A$  of order  $2^n$ . Show that  $H^1(G, A) = 0$  if and only if  $n = 2k$  and  $|A^G| = 2^k$ . [In  $E = A \rtimes G$  show that  $(a, x)$  is an element of order 2 if and only if  $a \in A^G$ , where  $G = \langle x \rangle$ . Then compare the number of complements to  $A$  with the number of  $E$ -conjugates of  $x$ .]
6. (*Thompson Transfer Lemma*) Let  $G$  be a finite group of even order, let  $T$  be a Sylow 2-subgroup of  $G$ , let  $M \leq T$  with  $|T : M| = 2$ , and let  $x$  be an element of order 2 in  $G$ . Show that if  $G$  has no subgroup of index 2 then  $M$  contains some  $G$ -conjugate of  $x$  as follows:
  - (a) Let  $\text{Ver} : G/[G, G] \rightarrow T/[T, T]$  be the transfer homomorphism. Show that
$$\text{Ver}(x) = \prod_g g^{-1}xg \text{ mod } [T, T]$$

where the product is over representatives of the cosets  $gT$  that are fixed under left multiplication by  $x$ .

  - (b) Show that under left multiplication  $x$  fixes an odd number of left cosets of  $T$  in  $G$ .
  - (c) Show that if  $G$  has no subgroup of index 2 then  $\text{Ver}(x) \in M/[T, T]$ . Deduce that for some  $g \in G$  we must have  $g^{-1}xg \in M$ . [Consider the product  $\text{Ver}(x)$  in the group  $T/M$  of order 2.]
7. Let  $H$  be a subgroup of  $G$  and let  $x \in G$ . The transfer  $\text{Ver} : G/[G, G] \rightarrow H/[H, H]$  may be computed as follows: let  $\mathcal{O}_1, \mathcal{O}_2, \dots, \mathcal{O}_k$  be the distinct orbits of  $x$  acting by left multiplication on the left cosets of  $H$  in  $G$ , let  $\mathcal{O}_i$  have length  $n_i$  and let  $g_i H$  be any representative of  $\mathcal{O}_i$ .

- (a) Show that  $\mathcal{O}_i = \{g_i H, xg_i H, x^2 g_i H, \dots, x^{n_i-1} g_i H\}$  and that  $g_i^{-1} x^{n_i} g_i \in H$ .  
 (b) Show that  $\text{Ver}(x) = \prod_{i=1}^k g_i^{-1} x^{n_i} g_i \pmod{[H, H]}$ .
8. Assume the center,  $Z(G)$ , of  $G$  is of index  $m$ . Prove that  $\text{Ver}(x) = x^m$ , for all  $x \in G$ , where  $\text{Ver}$  is the transfer homomorphism from  $G/[G, G]$  to  $Z(G)$ . [Use the preceding exercise.]
9. Let  $p$  be a prime, let  $n \geq 3$ , and let  $V$  be an  $n$ -dimensional vector space over  $\mathbb{F}_p$  with basis  $v_1, v_2, \dots, v_n$ . Let  $V$  be a module for the symmetric group  $S_n$ , where each  $\pi \in S_n$  permutes the basis in the natural way:  $\pi(v_i) = v_{\pi(i)}$ .
- (a) Show that  $|H^1(S_n, V)| = \begin{cases} 0, & \text{if } p \neq 2 \\ 2, & \text{if } p = 2 \end{cases}$ . [Use Shapiro's Lemma.]  
 (b) Show that  $H^1(A_n, V) = 0$  for all primes  $p$ .
10. Let  $V$  be the natural permutation module for  $S_n$  over  $\mathbb{F}_2$ ,  $n \geq 3$ , as described in the preceding exercise, and let  $W = \{a_1 v_1 + \dots + a_n v_n \mid a_1 + \dots + a_n = 0\}$  (the “trace zero” submodule of  $V$ ). Show that if  $n$  is even then  $H^1(A_n, W) \neq 0$ . [Show that in the semidirect product  $V \rtimes A_n$  the element  $v_1$  induces a nontrivial outer automorphism on  $E = W \rtimes A_n$  that stabilizes the series  $1 \trianglelefteq W \trianglelefteq E$ .]
11. Let  $F$  be a field of characteristic not dividing  $n$  and let  $\alpha$  be any nonzero element in  $F$ . Let  $K$  be a Galois extension of  $F$  containing the splitting field of  $x^n - \alpha$ , and let  $\sqrt[n]{\alpha}$  be a fixed  $n^{\text{th}}$  root of  $\alpha$  in  $K$ .
- (a) Prove that  $\sigma(\sqrt[n]{\alpha})/\sqrt[n]{\alpha}$  is an  $n^{\text{th}}$  root of unity.  
 (b) Prove that the function  $f(\sigma) = \sigma(\sqrt[n]{\alpha})/\sqrt[n]{\alpha}$  is a 1-cocycle of  $G$  with values in the group  $\mu_n$  of  $n^{\text{th}}$  roots of unity in  $K$  (note  $\mu_n$  is not assumed to be contained in  $F$ ).  
 (c) Prove that the 1-cocycle obtained by a different choice of  $n^{\text{th}}$  root of  $\alpha$  in  $K$  differs from the 1-cocycle in (b) by a 1-coboundary.
12. Let  $F$  be a field of characteristic not dividing  $n$  that contains the  $n^{\text{th}}$  roots of unity, and suppose  $L/F$  is a Galois extension with abelian Galois group of exponent dividing  $n$ . Prove that  $L$  is the composite of cyclic extensions of  $F$  whose degrees are divisors of  $n$  and use this to prove that there is a bijection between the subgroups of the multiplicative group  $F^\times/F^{\times n}$  and such extensions  $L$ .
13. The Galois group of the extension  $\mathbb{C}/\mathbb{R}$  is the cyclic group  $G = \langle \tau \rangle$  of order 2 generated by complex conjugation  $\tau$ . Prove that  $H^2(G, \mathbb{C}^\times) \cong \mathbb{R}^\times/\mathbb{R}^+ \cong \mathbb{Z}/2\mathbb{Z}$  where  $\mathbb{R}^+$  denotes the positive real numbers.
14. For any group  $G$  let  $\hat{G} = \text{Hom}(G, \mathbb{Q}/\mathbb{Z})$  denote its dual group.
- (a) If  $\varphi : G_1 \rightarrow G_2$  is a group homomorphism prove that composition with  $\varphi$  induces a homomorphism  $\hat{\varphi} : \hat{G}_2 \rightarrow \hat{G}_1$  on their dual groups.  
 (b) For any fixed  $g$  in  $G$ , show that evaluation at  $g$  gives a homomorphism  $\varphi_g$  from  $\hat{G}$  to  $\mathbb{Q}/\mathbb{Z}$ .  
 (c) Prove that the map taking  $g \in G$  to  $\varphi_g$  in (b) defines a homomorphism from  $G$  to its *double dual* ( $\widehat{\hat{G}}$ ).  
 (d) Prove that if  $G$  is a finite abelian group then the homomorphism in (c) is an isomorphism of  $G$  with its double dual. (By Exercise 14 in Section 5.2 the group  $G$  is (noncanonically) isomorphic to its dual  $\hat{G}$ . This shows that  $G$  is *canonically* isomorphic to its double dual — the isomorphism is independent of any choice of generators for  $G$ .)  
 (e) If  $\psi : \hat{G}_2 \rightarrow \hat{G}_1$  is a homomorphism where  $G_1$  and  $G_2$  are finite abelian groups, then by (a) and (d) there is an induced homomorphism  $\varphi : G_1 \rightarrow G_2$ . Prove that

$\varphi(g_1) = g_2$  if  $\chi(g_2) = \chi'(g_1)$  for  $\chi' = \psi(\chi)$ .

15. Use Gauss' Lemma in the computation of the transfer map for  $\mathbb{F}_p^\times$  to  $\{\pm 1\}$  to prove that 2 is a square modulo the odd prime  $p$  if and only if  $p \equiv \pm 1 \pmod{8}$ . [Count how many elements in  $2, 4, \dots, p-1$  are greater than  $(p-1)/2$ .]

## 17.4 GROUP EXTENSIONS, FACTOR SETS AND $H^2(G, A)$

If  $A$  is a  $G$ -module then from the definition of the coboundary map  $d_2$  in equation (18) a function  $f$  from  $G \times G$  to  $A$  is a 2-cocycle if it satisfies the identity

$$f(g, h) + f(gh, k) = g \cdot f(h, k) + f(g, hk) \quad \text{for all } g, h, k \in G. \quad (17.26)$$

Equivalently, a 2-cocycle is determined by a collection of elements  $\{a_{g,h}\}_{g,h \in G}$  of elements in  $A$  satisfying  $a_{g,h} + a_{gh,k} = g \cdot a_{h,k} + a_{g,hk}$  for  $g, h, k \in G$  (and then the 2-cocycle  $f$  is the function sending  $(g, h)$  to  $a_{g,h}$ ).

A 2-cochain  $f$  is a coboundary if there is a function  $f_1 : G \rightarrow A$  such that

$$f(g, h) = gf_1(h) - f_1(gh) + f_1(g), \quad \text{for all } g, h \in G \quad (17.27)$$

i.e.,  $f$  is the image under  $d_1$  of the 1-cochain  $f_1$ .

One of the main results of this section is to make a connection between the 2-cocycles  $Z^2(G, A)$  and the *factor sets* associated to a group extension of  $G$  by  $A$ , which arise when considering the effect of choosing different coset representatives in defining the multiplication in the extension. In particular, we shall show that there is a bijection between equivalence classes of group extensions of  $G$  by  $A$  (with the action of  $G$  on  $A$  fixed) and the elements of  $H^2(G, A)$ .

We first observe some basic facts about extensions. Let  $E$  be any group extension of  $G$  by  $A$ ,

$$1 \longrightarrow A \xrightarrow{\iota} E \xrightarrow{\pi} G \longrightarrow 1. \quad (17.28)$$

The extension (28) determines an action of  $G$  on  $A$ , as follows. For each  $g \in G$  let  $e_g$  be an element of  $E$  mapping onto  $g$  by  $\pi$  (the choice of such a set of representatives for  $G$  in  $E$  is called a set-theoretic *section* of  $\pi$ ). The element  $e_g$  acts by conjugation on the normal subgroup  $\iota(A)$  of  $E$ , mapping  $\iota(a)$  to  $e_g \iota(a) e_g^{-1}$ . Any other element in  $E$  that maps to  $g$  is of the form  $e_g \iota(a_1)$  for some  $a_1 \in A$ , and since  $\iota(A)$  is abelian, conjugation by this element on  $\iota(A)$  is the same as conjugation by  $e_g$ , so is independent of the choice of representative for  $g$ . Hence  $G$  acts on  $\iota(A)$ , and so also on  $A$  since  $\iota$  is injective. Since conjugation is an automorphism, the extension (28) defines  $A$  as a  $G$ -module.

Recall from Section 10.5 that two extensions  $1 \rightarrow A \xrightarrow{\iota_1} E_1 \xrightarrow{\pi_1} G \rightarrow 1$  and  $1 \rightarrow A \xrightarrow{\iota_2} E_2 \xrightarrow{\pi_2} G \rightarrow 1$  are *equivalent* if there is a group isomorphism  $\beta : E_1 \rightarrow E_2$  such that the following diagram commutes:

$$\begin{array}{ccccccc} 1 & \longrightarrow & A & \xrightarrow{\iota_1} & E_1 & \xrightarrow{\pi_1} & G \longrightarrow 1 \\ & & \downarrow \text{id} & & \downarrow \beta & & \downarrow \text{id} \\ 1 & \longrightarrow & A & \xrightarrow{\iota_2} & E_2 & \xrightarrow{\pi_2} & G \longrightarrow 1. \end{array} \quad (17.29)$$

In this case we simply say  $\beta$  is the equivalence between the two extensions. As noted in Section 10.5, equivalence of extensions is reflexive, symmetric and transitive. We also observe that

*equivalent extensions define the same G-module structure on A.*

To see this assume (29) is an equivalence, let  $g$  be any element of  $G$  and let  $e_g$  be any element of  $E_1$  mapping onto  $g$  by  $\pi_1$ . The action of  $g$  on  $A$  given by conjugation in  $E_1$  maps each  $a$  to  $\iota_1^{-1}(e_g \iota_1(a) e_g^{-1})$ . Let  $e'_g = \beta(e_g)$ . Since the diagram commutes,  $\pi_2(e'_g) = g$ , so the action of  $g$  on  $A$  in the second extension is given by conjugation by  $e'_g$ . This conjugation maps  $a$  to  $\iota_2^{-1}(e'_g \iota_2(a) e'^{-1}_g)$ . Since  $\iota_1, \iota_2$  and  $\beta$  are injective, the two actions of  $g$  on  $a$  are equal if and only if they result in the same image in  $E_2$ , i.e.,  $\beta \circ \iota_1(\iota_1^{-1}(e_g \iota_1(a) e_g^{-1})) = e'_g \iota_2(a) e'^{-1}_g$ . This equality is now immediate from the definition of  $e'_g$  and the commutativity of the diagram.

We next see how an extension as in (28) defines a 2-cocycle in  $Z^2(G, A)$ . For simplicity we identify  $A$  as a subgroup of  $E$  via  $\iota$  and we identify  $G$  as  $E/A$  via  $\pi$ .

**Definition.** A map  $\mu : G \rightarrow E$  with  $\pi \circ \mu(g) = g$  and  $\mu(1) = 0$ , i.e., so that for each  $g \in G$ ,  $\mu(g)$  is a representative of the coset  $Ag$  of  $E$  and the identity of  $E$  (which is the zero of  $A$ ) represents the identity coset, is called a *normalized section* of  $\pi$ .

Fix a section  $\mu$  of  $\pi$  in (28). Each element of  $E$  may be written uniquely in the form  $a\mu(g)$ , where  $a \in A$  and  $g \in G$ . For  $g, h \in G$  the product  $\mu(g)\mu(h)$  in  $E$  lies in the coset  $Ag h$ , so there is a unique element  $f(g, h)$  in  $A$  such that

$$\mu(g)\mu(h) = f(g, h)\mu(gh) \quad \text{for all } g, h \in G. \quad (17.30)$$

If in addition  $\mu$  is normalized at the identity we also have

$$f(g, 1) = 0 = f(1, g) \quad \text{for all } g \in G. \quad (17.31)$$

**Definition.** The function  $f$  defined by equation (30) is called the *factor set* for the extension  $E$  associated to the section  $\mu$ . If  $f$  also satisfies (31) then  $f$  is called a *normalized factor set*.

We shall see in the examples following that it is possible for different sections  $\mu$  to give the same factor set  $f$ .

We now verify that the factor set  $f$  is in fact a 2-cocycle. First note that the group operation in  $E$  may be written

$$\begin{aligned} (a_1\mu(g))(a_2\mu(h)) &= (a_1 + \mu(g)a_2\mu(g)^{-1})\mu(g)\mu(h) \\ &= (a_1 + g \cdot a_2)(\mu(g)\mu(h)) \\ &= (a_1 + g \cdot a_2 + f(g, h))\mu(gh) \end{aligned} \quad (17.32)$$

where  $g \cdot a_2$  denotes the  $G$ -module action of  $g$  on  $a_2$  given by conjugation in  $E$ . Now use (32) and the associative law in  $E$  to compute the product  $\mu(g)\mu(h)\mu(k)$  in two different ways:

$$\begin{aligned} (\mu(g)\mu(h))\mu(k) &= (f(g, h) + f(gh, k))\mu(ghk) \\ \mu(g)(\mu(h)\mu(k)) &= (gf(h, k) + f(g, hk))\mu(ghk). \end{aligned} \quad , \quad (17.33)$$

It follows that the factors in  $A$  of the two right hand sides in (33) are equal for every  $g, h, k \in G$ , and this is precisely the 2-cocycle condition (26) for  $f$ . This shows that the factor set associated to the extension  $E$  and any choice of section  $\mu$  is an element in  $Z^2(G, A)$ .

We next see how the factor set  $f$  depends on the choice of section  $\mu$ . Suppose  $\mu'$  is another section for the same extension  $E$  in (28), and let  $f'$  be its associated factor set. Then for all  $g \in G$  both  $\mu(g)$  and  $\mu'(g)$  lie in the same coset  $Ag$ , so there is a function  $f_1 : G \rightarrow A$  such that  $\mu'(g) = f_1(g)\mu(g)$  for all  $g$ . Then

$$\mu'(g)\mu'(h) = f'(g, h)\mu'(gh) = (f'(g, h) + f_1(gh))\mu(gh).$$

We also have

$$\begin{aligned}\mu'(g)\mu'(h) &= (f_1(g)\mu(g))(f_1(h)\mu(h)) = (f_1(g) + g \cdot f_1(h))(\mu(g)\mu(h)) \\ &= (f_1(g) + g \cdot f_1(h) + f(g, h))\mu(gh).\end{aligned}$$

Equating the factors in  $A$  in these two expressions for  $\mu'(g)\mu'(h)$  shows that

$$f'(g, h) = f(g, h) + (gf_1(h) - f_1(gh) + f_1(g)) \quad \text{for all } g, h \in G,$$

in other words  $f$  and  $f'$  differ by the 2-coboundary of  $f_1$  as in (27).

We have shown that the factor sets associated to the extension  $E$  corresponding to different choices of sections give 2-cocycles in  $Z^2(G, A)$  that differ by a coboundary in  $B^2(G, A)$ . Hence associated to the extension  $E$  is a well defined cohomology class in  $H^2(G, A)$  determined by the factor set in (30) for any choice of section  $\mu$ .

If the extension  $E$  of  $G$  by  $A$  is a *split* extension (which is to say that  $E = A \rtimes G$  is the semidirect product of  $G$  by  $A$  with the given conjugation action of  $G$  on  $A$ ), then there is a section  $\mu$  of  $G$  that is a *homomorphism* from  $G$  to  $E$ . In this case the factor set  $f$  in (30) is identically 0:  $f(g, h) = 0$  for all  $g, h \in G$ . Hence the cohomology class in  $H^2(G, A)$  defined by a split extension is the trivial class.

Suppose now that  $\beta$  is an equivalence between the extension in (28) and an extension  $E'$ :

$$\begin{array}{ccccccc} 1 & \longrightarrow & A & \xrightarrow{\iota} & E & \xrightarrow{\pi} & G \longrightarrow 1 \\ & & \downarrow \text{id} & & \downarrow \beta & & \downarrow \text{id} \\ 1 & \longrightarrow & A & \xrightarrow{\iota'} & E' & \xrightarrow{\pi'} & G \longrightarrow 1. \end{array}$$

If  $\mu$  is a section of  $\pi$ , then  $\mu' = \beta \circ \mu$  is a section of  $\pi'$ , so what we have just proved can be used to determine the cohomology class in  $H^2(G, A)$  corresponding to  $E'$ . Applying the homomorphism  $\beta$  to equation (30) gives

$$\beta(\mu(g))\beta(\mu(h)) = \beta(f(g, h))\beta(\mu(gh)) \quad \text{for all } g, h \in G.$$

Since  $\beta$  restricts to the identity map on  $A$ , this is

$$\mu'(g)\mu'(h) = f(g, h)\mu'(gh) \quad \text{for all } g, h \in G,$$

which shows that the factor set for  $E'$  associated to  $\mu'$  is the same as the factor set for  $E$  associated to  $\mu$ . This proves that equivalent extensions define the same cohomology class in  $H^2(G, A)$ .

We next show how this procedure may be reversed: Given a class in  $H^2(G, A)$  we construct an extension  $E_f$  whose corresponding factor set is in the given class in  $H^2(G, A)$ . The process generalizes the semidirect product construction of Section 5.5 (which is the special case when  $f$  is the zero cocycle representing the trivial class).

Note first that any 2-cocycle arising from the factor set of an extension as above where the section  $\mu$  is normalized satisfies the condition in (31).

**Definition.** A 2-cocycle  $f$  such that  $f(g, 1) = 0 = f(1, g)$  for all  $g \in G$  is called a *normalized 2-cocycle*.

The construction of  $E_f$  is a little simpler when  $f$  is a normalized cocycle and for simplicity we indicate the construction in this case (the minor modifications necessary when  $f$  is not normalized are indicated in Exercise 4).

We first see that any 2-cocycle  $f$  lies in the same cohomology class as a normalized 2-cocycle. Let  $d_1 f_1$  be the 2-coboundary of the constant function  $f_1$  on  $G$  whose value is  $f(1, 1)$ . Then  $f(1, 1) = d_1 f_1(1, 1)$ , and one easily checks from the 2-cocycle condition that  $f - d_1 f_1$  is normalized.

We may therefore assume that our cohomology class in  $H^2(G, A)$  is represented by the normalized 2-cocycle  $f$ . Let  $E_f$  be the set  $A \times G$ , and define a binary operation on  $E_f$  by

$$(a_1, g)(a_2, h) = (a_1 + g \cdot a_2 + f(g, h), gh) \quad (17.34)$$

where, as usual,  $g \cdot a_2$  denotes the module action of  $G$  on  $A$ . It is straightforward to check that the group axioms hold: Since  $f$  is normalized, the identity element is  $(0, 1)$  and inverses are given by

$$(a, g)^{-1} = (-g^{-1} \cdot a - f(g^{-1}, g), g^{-1}). \quad (17.35)$$

The cocycle condition implies the associative law by calculations similar to (32) and (33) earlier — the details are left as exercises.

Since  $f$  is a normalized 2-cocycle,  $A^* = \{(a, 1) \mid a \in A\}$  is a subgroup of  $E_f$ , and the map  $\iota^* : a \mapsto (a, 1)$  is an isomorphism from  $A$  to  $A^*$ . Moreover, from (34) and (35) it follows that

$$(0, g)(a, 1)(0, g)^{-1} = (g \cdot a, 1) \quad \text{for all } g \in G \text{ and all } a \in A. \quad (17.36)$$

Since  $E_f$  is generated by  $A^*$  together with the set of elements  $(0, g)$  for  $g \in G$ , (36) implies that  $A^*$  is a normal subgroup of  $E_f$ . Furthermore, it is immediate from (34) that the map  $\pi^* : (a, g) \mapsto g$  is a surjective homomorphism from  $E_f$  to  $G$  with kernel  $A^*$ , i.e.,  $E_f/A^* \cong G$ . Thus

$$1 \longrightarrow A \xrightarrow{\iota^*} E_f \xrightarrow{\pi^*} G \longrightarrow 1 \quad (17.37)$$

is a specific extension of  $G$  by  $A$ , where (36) ensures also that the action of  $G$  on  $A$  by conjugation in this extension is the module action specified in determining the 2-cocycle  $f$  in  $H^2(G, A)$ . The extension sequence (37) shows that this extension has the normalized section  $\mu(g) = (0, g)$  whose corresponding normalized factor set is  $f$ . Note that this proves not only that every cohomology class in  $H^2(G, A)$  arises from

some extension  $E$ , but that every normalized 2-cocycle arises as the normalized factor set of some extension.

Finally, suppose  $f'$  is another normalized 2-cocycle in the same cohomology class in  $H^2(G, A)$  as  $f$  and let  $E_{f'}$  be the corresponding extension. If  $f$  and  $f'$  differ by the coboundary of  $f_1 : G \rightarrow A$  then  $f(g, h) - f'(g, h) = gf_1(h) - f_1(gh) + f_1(g)$  for all  $g, h \in G$ . Setting  $g = h = 1$  shows that  $f_1(1) = 0$ . Define

$$\beta : E_f \longrightarrow E_{f'} \quad \text{by} \quad \beta((a, g)) = (a + f_1(g), g).$$

It is immediate that  $\beta$  is a bijection, and

$$\begin{aligned} \beta((a_1, g)(a_2, h)) &= \beta((a_1 + g \cdot a_2 + f(g, h), gh)) \\ &= (a_1 + g \cdot a_2 + f(g, h) + f_1(gh), gh) \\ &= (a_1 + f_1(g) + g \cdot (a_2 + f_1(h)) + f'(g, h), gh) \\ &= (a_1 + f_1(g), g)(a_2 + f_1(h), h) = \beta((a_1, g))\beta((a_2, h)) \end{aligned}$$

shows that  $\beta$  is an isomorphism from  $E_f$  to  $E_{f'}$ .

The restriction of  $\beta$  to  $A$  is given by  $\beta((a, 1)) = (a + f_1(1), 1) = (a, 1)$ , so  $\beta$  is the identity map on  $A$ . Similarly  $\beta$  is the identity map on the second component of  $(a, g)$ , so  $\beta$  induces the identity map on the quotient  $G$ . It follows that  $\beta$  defines an equivalence between the extensions  $E_f$  and  $E_{f'}$ . This shows that the equivalence class of the extension  $E_f$  depends only on the cohomology class of  $f$  in  $H^2(G, A)$ .

We summarize this discussion in the following theorem.

**Theorem 36.** Let  $A$  be a  $G$ -module. Then

- (1) A function  $f : G \times G \rightarrow A$  is a normalized factor set of some extension  $E$  of  $G$  by  $A$  (with conjugation given by the  $G$ -module action on  $A$ ) if and only if  $f$  is a normalized 2-cocycle in  $Z^2(G, A)$ .
- (2) There is a bijection between the equivalence classes of extensions  $E$  as in (1) and the cohomology classes in  $H^2(G, A)$ . The bijection takes an extension  $E$  into the class of a normalized factor set  $f$  for  $E$  associated to any normalized section  $\mu$  of  $G$  into  $E$ , and takes a cohomology class  $c$  in  $H^2(G, A)$  to the extension  $E_f$  defined by the extension (37) for any normalized cocycle  $f$  in the class  $c$ .
- (3) Under the bijection in (2), split extensions correspond to the trivial cohomology class.

**Corollary 37.** Every extension of  $G$  by the abelian group  $A$  splits if and only if  $H^2(G, A) = 0$ .

**Corollary 38.** If  $A$  is a finite abelian group and  $(|A|, |G|) = 1$  then every extension of  $G$  by  $A$  splits.

*Proof:* This follows immediately from Corollary 29 in Section 2.

We can use Corollary 38 to prove the same result without the restriction that  $A$  be an abelian group.

**Theorem 39. (Schur's Theorem)** If  $E$  is any finite group containing a normal subgroup  $N$  whose order and index are relatively prime, then  $N$  has a complement in  $E$ .

**Remark:** Recall that a subgroup whose order and index are relatively prime is called a *Hall subgroup*, so Schur's Theorem says that every normal Hall subgroup has a complement that splits the group as a semidirect product.

**Proof:** We use induction on the order of  $E$ . Since we may assume  $N \neq 1$ , let  $p$  be a prime dividing  $|N|$  and let  $P$  be a Sylow  $p$ -subgroup of  $N$ . Let  $E_0$  be the normalizer in  $E$  of  $P$  and let  $N_0 = N \cap E_0$ . By Frattini's Argument (Proposition 6 in Section 6.1)  $E = E_0N$ . It follows from the Second Isomorphism Theorem that  $N_0$  is a (normal) Hall subgroup of  $E_0$  and  $|E_0 : N_0| = |E : N|$  (cf. Exercise 10 of Section 3.3).

If  $E_0 < E$ , then by induction applied to  $N_0$  in  $E_0$  we obtain that  $E_0$  contains a complement  $K$  to  $N_0$ . Since  $|K| = |E_0 : N_0|$ ,  $K$  is also a complement to  $N$  in  $E$ , as needed. Thus we may assume  $E_0 = E$ , i.e.,  $P$  is normal in  $E$ .

Since the center of  $P$ ,  $Z(P)$ , is characteristic in  $P$ , it is normal in  $E$  (cf. Section 4.4). If  $Z(P) = N$ , then  $N$  is abelian and the theorem follows from Corollary 38. Thus we may assume  $Z(P) \neq N$ . Let bars denote passage to the quotient group  $\bar{E} = E/Z(P)$ . Then  $\bar{N}$  is a normal Hall subgroup of  $\bar{E}$ . By induction it has a complement  $\bar{K}$  in  $\bar{E}$ . Let  $E_1$  be the complete preimage of  $\bar{K}$  in  $E$ . Then  $|E_1| = |\bar{K}| |Z(P)| = |E/N| |Z(P)|$ , so  $Z(P)$  is a normal Hall subgroup of  $E_1$ . By induction  $Z(P)$  has a complement in  $E_1$  which is seen by order considerations to also be a complement to  $N$  in  $E$ . This completes the proof.

## Examples

- (1) If  $G = Z_2$  and  $A = \mathbb{Z}/2\mathbb{Z}$  then  $G$  acts trivially on  $A$  and so  $H^2(G, A) = A^G/NA = \mathbb{Z}/2\mathbb{Z}$  by the computation of the cohomology of cyclic groups in Section 2, so by Theorem 36 there are precisely two inequivalent extensions of  $G$  by  $A$ . These are the cyclic group of order 4 and the Klein 4-group, the latter being split and hence corresponding to the trivial class in  $H^2$ .
- (2) If  $G = \langle g \rangle \cong Z_2$  and  $A = \langle a \rangle \cong \mathbb{Z}/4\mathbb{Z}$  is a group of order 4 on which  $G$  acts trivially, then  $H^2(G, A) = A/2A \cong \mathbb{Z}/2\mathbb{Z}$  by the computation of the cohomology of cyclic groups. As in the previous example there are two inequivalent extensions of  $G$  by  $A$ ; evidently these are the groups  $Z_8$  and  $Z_4 \times Z_2$ , the latter split extension corresponding to the trivial cohomology class.

If  $E = \langle r \rangle \times \langle s \rangle$  denotes the split extension of  $G$  by  $A$ , where  $|r| = 4$  and  $|s| = 2$ , then  $\mu_i(g) = r^i s$  for  $i = 0, \dots, 3$  give the four normalized sections of  $G$  in  $E$ . The sections  $\mu_0, \mu_2$  both give the zero factor set  $f$ . The sections  $\mu_1, \mu_3$  both give the factor set  $f'$  with  $f'(g, g) = a^2 \in A$ . Both  $f$  and  $f'$  give normalized 2-cocycles lying in the trivial cohomology class of  $H^2(G, A)$ . The extension  $E_f$  corresponding to the zero 2-cocycle  $f$  is the group with the elements  $(a, 1)$  and  $(1, g)$  as the usual generators (of orders 4 and 2, respectively) for  $Z_4 \times Z_2$ . In  $E_f$ , however,  $(a, 1)$  has order 4 but so does  $(1, g)$  since  $(1, g)^2 = (f'(g, g), g^2) = (a^2, 1)$ . The 2-cocycles  $f$  and  $f'$  differ by the coboundary  $f_1$  with  $f_1(1) = 1$  and  $f_1(g) = r$ . The isomorphism  $\beta(a, g) = (a + f_1(g), g)$  from  $E_f$  to  $E_{f'}$  maps the generators  $(a, 1)$  and  $(1, g)$  of  $E_f$  to the generators  $(a, 1)$  and  $(a, g)$  of  $E_{f'}$  and gives the explicit equivalence of these two extensions.

The situation where  $G$  acts on  $A$  by inversion is handled in Exercise 3.

- (3) Suppose  $G = Z_2$  and  $A$  is the Klein 4-group. If  $G$  acts nontrivially on  $A$  then  $G$  interchanges two of the nonidentity elements, say  $a$  and  $b$ , of  $A$  and fixes the third nonidentity element  $c$ . Then  $A^G = NA = \{1, c\}$  and so  $H^2(G, A) = 0$ , and so every extension  $E$  of  $G$  by  $A$  splits. This can be seen directly, as follows. Since the action is nontrivial, such a group must be nonabelian, hence must be  $D_8$ . From the lattice of  $D_8$  in Section 2.5 one sees that for each Klein 4-group there is a subgroup of order 2 in  $D_8$  not contained in the 4-group and that subgroup splits the extension.

If  $G$  acts trivially on  $A$  then  $H^2(G, A) = A/2A \cong A$ , so there are 4 inequivalent extensions of  $G$  by  $A$  in this case. These are considered in Exercise 1.

### Example: (Groups of Order 8 and $H^2(Z_2 \times Z_2, \mathbb{Z}/2\mathbb{Z})$ )

Let  $G = \{1, a, b, c\}$  be the Klein 4-group and let  $A = \mathbb{Z}/2\mathbb{Z}$ . The 2-group  $G$  must act trivially on  $A$ . The elements of  $H^2(G, A)$  classify extensions  $E$  of order 8 which has a quotient group by some  $Z_2$  subgroup that is isomorphic to the Klein 4-group. Although there are, up to group isomorphism, only four such groups, we shall see that there are *eight* inequivalent extensions.

Since  $G \times G$  has 16 elements, we have  $|C^2(G, A)| = 2^{16}$ . The cocycle condition (26) here reduces to

$$f(g, h) + f(gh, k) = f(h, k) + f(g, hk) \quad \text{for all } g, h, k \in G. \quad (17.38)$$

The following relations hold for the subgroup  $Z^2(G, A)$  of cocycles:

- (1)  $f(g, 1) = f(1, g) = f(1, 1)$ , for all  $g \in G$
- (2)  $f(g, 1) + f(g, a) + f(g, b) + f(g, c) = 0$ , for all  $g \in G$
- (3)  $f(1, h) + f(a, h) + f(b, h) + f(c, h) = 0$ , for all  $h \in G$ .

The first of these come from (38) by setting  $h = k = 1$  and by setting  $g = h = 1$ . The other two relations come from (38) by setting  $g = h$  and  $h = k$ , respectively, using relations (1) and (2). It follows that every 2-cocycle  $f$  can be represented by a vector  $(\alpha, \beta, \gamma, \delta, \epsilon)$  in  $\mathbb{F}_2$  where

$$\begin{aligned} \alpha &= f(1, g) = f(g, 1), \text{ for all } g \in G, \\ \beta &= f(a, a), \quad \gamma = f(a, b), \quad \delta = f(b, a), \quad \epsilon = f(b, b) \end{aligned}$$

because the relations above then determine the remaining values of  $f$ :

$$\begin{aligned} f(a, c) &= \alpha + \beta + \gamma & f(b, c) &= \alpha + \delta + \epsilon & f(c, a) &= \alpha + \beta + \delta \\ f(c, b) &= \alpha + \gamma + \epsilon & f(c, c) &= \alpha + \beta + \gamma + \epsilon. \end{aligned}$$

It follows that  $|Z^2(G, A)| \leq 2^5$ . Although one could eventually show that every function satisfying these relations is a 2-cocycle (hence the order is exactly 32), this will follow from other considerations below.

A cocycle  $f$  is a coboundary if there is a function  $f_1 : G \rightarrow A$  such that

$$f(g, h) = f_1(h) - f_1(gh) + f_1(g), \quad \text{for all } g, h \in G.$$

This coboundary condition is easily seen to be equivalent to the conditions:

- (i)  $f(g, 1) = f(1, g) = f(g, g)$  for all  $g \in G$ , and
- (ii)  $f(g, h) = f(g', h')$  whenever  $g, h$  are distinct nonidentity elements and so are  $g', h'$ .

These relations are equivalent to  $\alpha = \beta = \epsilon$  and  $\gamma = \delta$ . Thus  $B^2(G, A)$  consists of the vectors  $(\alpha, \alpha, \gamma, \gamma, \alpha)$ , and so  $H^2(G, A)$  has dimension at most 3 (i.e., order at most  $2^3 = 8$ ). It is easy to see that  $\{(0, \beta, \gamma, 0, \epsilon)\}$  with  $\beta, \gamma$ , and  $\epsilon$  in  $\mathbb{F}_2$  gives a set of representatives for  $Z^2(G, A)/B^2(G, A)$ , and each of these representative cocycles is normalized. We

now prove  $|H^2(G, A)| = 8$  (and also that  $|Z^2(G, A)| = 2^5$ ) by explicitly exhibiting eight inequivalent group extensions,

Suppose  $E$  is an extension of  $G$  by  $A$ , where for simplicity we assume  $A \leq E$ . If  $\mu : G \rightarrow E$  is a section, the factor set for  $E$  associated to  $\mu$  satisfies

$$\mu(g)\mu(h) = f(g, h)\mu(gh).$$

The group  $E$  is generated by  $\mu(a)$ ,  $\mu(b)$  and  $A$ , and  $A$  is contained in the center of  $E$  since  $G$  acts trivially on  $A$ . Hence  $E$  is abelian if and only if  $\mu(a)\mu(b) = \mu(b)\mu(a)$ , which by the relation above occurs if and only if  $f(a, b) = f(b, a)$ . If  $g$  is a nonidentity element in  $G$ , we also see from the relation above that  $\mu(g)$  is an element of order 2 in  $E$  if and only if  $f(g, g) = 0$ . Because  $A$  is contained in the center of  $E$ , both elements in any nonidentity coset  $A\mu(g)$  have the same order (either 2 or 4).

There are four groups of order 8 containing a normal subgroup of order 2 with quotient group isomorphic to the Klein 4-group:  $Z_2 \times Z_2 \times Z_2$ ,  $Z_4 \times Z_2$ ,  $D_8$ , and  $Q_8$ .

The group  $E \cong Z_2 \times Z_2 \times Z_2$  is the split extension of  $G$  by  $A$  and has  $f = 0$  as factor set.

When  $E \cong Q_8$ , in the usual notation for the quaternion group  $A = \langle -1 \rangle$ . In this (non-abelian) group every nonidentity coset consists of elements of order 4, and this property is unique to  $Q_8$ , so the resulting factor set  $f$  satisfies  $f(g, g) \neq 0$  for all nonidentity elements in  $G$ .

When  $E \cong Z_4 \times Z_2 = \langle x \rangle \times \langle y \rangle$  we must have  $A = \langle x^2 \rangle$ . The cosets  $Ax$  and  $Axy$  both consist of elements of order 4, and the coset  $Ay$  consists of elements of order 2, so exactly one of  $\mu(a)$ ,  $\mu(b)$  or  $\mu(c)$  is an element of order 2 and the other two must be of order 4. This suggests three homomorphisms from  $E$  to  $G$ , defined on generators by

$$\begin{aligned}\pi_1(y) &= a & \pi_1(x) &= b \\ \pi_2(y) &= b & \pi_2(x) &= a . \\ \pi_3(y) &= c & \pi_3(x) &= a\end{aligned}$$

Each of these homomorphisms maps surjectively onto  $G$ , has  $A$  as kernel, and has  $\mu(a)$  (respectively,  $\mu(b)$ ,  $\mu(c)$ ) an element of order 2 in  $E$ . Any isomorphism of  $E$  with itself that is the identity on  $A$  must take the unique nonidentity coset  $Ay$  of  $A$  consisting of elements of order 2 to itself. Hence any extension equivalent to the extension  $E_1$  defined by  $\pi_1$  also maps  $y$  to  $a$  (since the equivalence is the identity on  $G$ ). It follows that the three extensions defined by  $\pi_1$ ,  $\pi_2$  and  $\pi_3$  are inequivalent.

The situation when  $E \cong D_8 = \langle r, s \rangle$  is similar. In this case  $A = \langle r^2 \rangle$ , the cosets  $As$  and  $Asr$  consist of elements of order 2, and the coset  $Ar$  consists of elements of order 4. In this case exactly one of  $\mu(a)$ ,  $\mu(b)$  or  $\mu(c)$  is an element of order 4 and the other two are of order 2, suggesting the three homomorphisms defined on generators by

$$\begin{aligned}\pi_1(r) &= a & \pi_1(s) &= b \\ \pi_2(r) &= b & \pi_2(s) &= a . \\ \pi_3(r) &= c & \pi_3(s) &= a\end{aligned}$$

As before, the corresponding extensions are inequivalent.

The existence of 8 inequivalent extensions of  $G$  by  $A$  proves that  $|H^2(G, A)| = 8$ , and hence that these are a complete list of all the inequivalent extensions. In particular, the extension  $E'_1 \cong Z_4 \times Z_2$  defined by the homomorphism  $\pi'_1$  mapping  $y$  to  $a$  and  $x$  to  $c$  must be equivalent to the extension  $E_1$  above (and similarly for the other two extensions isomorphic to  $Z_4 \times Z_2$  and the three extensions for  $D_8$ ). This proves the existence of certain outer automorphisms for these groups, cf. Exercise 9.

*Remark:* For any prime  $p$  the cohomology groups of the elementary abelian group  $E_{p^m}$  with coefficients in the finite field  $\mathbb{F}_p$  may be determined by relating them to the cohomology groups of the factors in the direct product as mentioned at the end of Section 2. In general,  $H^2(E_{p^m}, \mathbb{F}_p)$  is a vector space over  $\mathbb{F}_p$  of dimension  $\frac{1}{2}m(m+1)$ . When  $p=2$  and  $m=2$  this is the result  $H^2(Z_2 \times Z_2, \mathbb{Z}/2\mathbb{Z}) \cong (\mathbb{Z}/2\mathbb{Z})^3$  above.

## Crossed Product Algebras and the Brauer Group

Suppose  $F$  is a field. Recall that an  $F$ -algebra  $B$  is a ring containing the field  $F$  in its center and the identity of  $B$  is the identity of  $F$ , cf. Section 10.1.

**Definition.** An  $F$ -algebra  $A$  is said to be *simple* if  $A$  contains no nontrivial proper (two sided) ideals. A *central simple  $F$ -algebra*  $A$  is a simple  $F$ -algebra whose center is  $F$ .

Among the easiest central simple  $F$ -algebras are the matrix algebras  $M_n(F)$  of  $n \times n$  matrices with coefficients in  $F$ .

If  $K/F$  is a finite Galois extension of fields with Galois group  $G = \text{Gal}(K/F)$ , then we can use the normalized 2-cocycles in  $Z^2(G, K^\times)$  to construct certain central simple  $K$ -algebras. The construction of these algebras from 2-cocycles and their classification in terms of  $H^2(G, K^\times)$  (cf. Theorem 42 below) are important applications of cohomological methods in number theory. Their construction in the case when  $G$  is cyclic was one of the precursors leading to the development of abstract cohomology.

Suppose  $f = \{a_{\sigma, \tau}\}_{\sigma, \tau \in G}$  is a normalized 2-cocycle in  $Z^2(G, K^\times)$ . Let  $B_f$  be the vector space over  $L$  having basis  $u_\sigma$  for  $\sigma \in G$ :

$$B_f = \left\{ \sum_{\sigma \in G} \alpha_\sigma u_\sigma \mid \alpha_\sigma \in K \right\}. \quad (17.39)$$

Define a multiplication on  $B_f$  by

$$u_\sigma \alpha = \sigma(\alpha) u_\sigma \quad u_\sigma u_\tau = a_{\sigma, \tau} u_{\sigma \tau} \quad (17.40)$$

for  $\alpha \in L$  and  $\sigma, \tau \in G$ . The second equation shows that the  $a_{\sigma, \tau}$  give a “factor set” for the elements  $u_\sigma$  in  $B_f$  and is one reason this terminology is used. Using this multiplication we find

$$(u_\sigma u_\tau) u_\rho = a_{\sigma, \tau} a_{\sigma \tau, \rho} u_{\sigma \tau \rho} \quad \text{and} \quad u_\sigma (u_\tau u_\rho) = \sigma(a_{\tau, \rho}) a_{\sigma, \tau \rho} u_{\sigma \tau \rho}.$$

Since  $a_{\sigma, \tau} a_{\sigma \tau, \rho} = \sigma(a_{\tau, \rho}) a_{\sigma, \tau \rho}$  is the multiplicative form of the cocycle condition (26), it follows that the multiplication defined in (40) is associative.

Since the cocycle is normalized we have  $a_{1, \sigma} = a_{\sigma, 1} = 1$  for all  $\sigma \in G$  and it follows from (40) that the element  $u_1$  is an identity in  $B_f$ . Identifying  $K$  with the elements  $\alpha u_1$  in  $B_f$ , we see that  $B_f$  is an  $F$ -algebra containing the field  $K$  and having dimension  $n^2$  over  $F$  if  $n = [K : F] = |G|$ .

**Proposition 40.** The  $F$ -algebra  $B_f$  with  $K$ -vector space basis  $u_\sigma$  in (39) and multiplication defined by (40) is a central simple  $F$ -algebra.

*Proof:* It remains to show that the center of  $B_f$  is  $F$  and that  $B_f$  contains no nonzero proper ideals. Suppose  $x = \sum_{\sigma \in G} \alpha_\sigma u_\sigma$  is an element in the center of  $B_f$ . Then  $x\beta = \beta x$  for  $\beta \in K$  shows that  $\sigma(\beta) = \beta$  if  $\alpha_\sigma \neq 0$ . Since there is an element  $\beta \in K$  not fixed by  $\sigma$  for any  $\sigma \neq 1$ , this shows that  $\alpha_\sigma = 0$  for all  $\sigma \neq 1$ , so  $x = \alpha_1 u_1$ . Then  $xu_\tau = u_\tau x$  if and only if  $\tau(\alpha_1) = \alpha_1$ , so if this is true for all  $\tau$  then we must have  $\alpha_1 = a \in K$ . Hence  $x = au_1$  and the center of  $B_f$  is  $F$ .

To show that  $B_f$  is simple, suppose  $I$  is a nonzero ideal in  $B_f$  and let

$$x = \alpha_{\sigma_1} u_{\sigma_1} + \cdots + \alpha_{\sigma_m} u_{\sigma_m}$$

be a nonzero element of  $I$  with the minimal number  $m$  of nonzero terms. If  $m > 1$  there is an element  $\beta \in K^\times$  with  $\sigma_m(\beta) \neq \sigma_{m-1}(\beta)$ . Then the element  $x - \sigma_m(\beta)x\beta^{-1}$  would be an element of the ideal  $I$  with the nonzero element  $(1 - \sigma_m(\beta)\sigma_{m-1}(\beta)^{-1})\alpha_{\sigma_{m-1}}$  as coefficient of  $u_{\sigma_{m-1}}$ , and would have fewer nonzero terms than  $x$  since the coefficient of  $u_{\sigma_m}$  is 0. It follows that  $m = 1$  and  $x = \alpha u_\sigma$  for some  $\alpha \in K$  and some  $\sigma$ . This element is a unit, with inverse  $\sigma^{-1}(\alpha^{-1})u_\sigma$ , so  $I = B_f$ , completing the proof.

**Definition.** The central simple  $F$ -algebra  $B_f$  defined by (39) and (40) is called the *crossed product algebra* for the factor set  $\{a_{\sigma,\tau}\}$ .

If  $f' = a'_{\sigma,\tau}$  is a normalized cocycle in the same cohomology class in  $H^2(G, K^\times)$  as  $a_{\sigma,\tau}$  then there are elements  $b_\sigma \in K^\times$  with

$$a'_{\sigma,\tau} = a_{\sigma,\tau}(\sigma(b_\tau)b_{\sigma\tau}^{-1}b_\sigma)$$

(the multiplicative form of the coboundary condition (27)). If  $B_{f'}$  is the  $F$ -algebra with  $K$ -basis  $v_\sigma$  defined from this cocycle as in (39) and (40), then the  $K$ -vector space homomorphism  $\varphi$  defined by mapping  $u'_\sigma$  to  $b_\sigma u_\sigma$  satisfies

$$\begin{aligned} \varphi(u'_\sigma u'_\tau) &= \varphi(a'_{\sigma,\tau} u'_{\sigma\tau}) = d'_{\sigma,\tau} b_{\sigma\tau} u_{\sigma\tau} = b_\sigma \sigma(b_\tau) u_\sigma u_\tau \\ &= (b_\sigma u_\sigma)(b_\tau u_\tau) = \varphi(u'_\sigma) \varphi(u'_\tau). \end{aligned}$$

It follows that  $\varphi$  is an  $F$ -algebra isomorphism from  $B_{f'}$  to  $B_f$ .

We have shown that every cohomology class  $c$  in  $H^2(G, K^\times)$  defines an isomorphism class of central simple  $F$ -algebras, namely the isomorphism class of any crossed product algebra for a normalized cocycle  $\{a_{\sigma,\tau}\}$  representing the class  $c$ . The next result shows that the trivial cohomology class corresponds to the isomorphism class containing  $M_n(F)$ .

**Proposition 41.** The crossed product algebra for the trivial cohomology class in  $H^2(G, K^\times)$  is isomorphic to the matrix algebra  $M_n(F)$  where  $n = [K : F]$ .

*Proof:* If  $\alpha \in K$  then multiplication by  $\alpha$  defines a linear transformation  $T_\alpha$  of  $K$  viewed as an  $n$ -dimensional vector space over  $F$ . Similarly, every automorphism  $\sigma \in G$  defines an  $F$ -linear transformation  $T_\sigma$  of  $K$ , and we may view both  $T_\alpha$  and  $T_\sigma$  as

elements of  $M_n(F)$  by choosing a basis for  $K$  over  $F$ . If  $B_0$  denotes the crossed product algebra for the trivial factor set ( $a_{\sigma,\tau} = 1$  for all  $\sigma, \tau \in G$ ), consider the additive map  $\varphi : B_0 \rightarrow M_n(F)$  defined by  $\varphi(\alpha u_\sigma) = T_\sigma T_\alpha$ . Since  $T_{\alpha a} = a T_\alpha$  for  $a \in F$ , the map  $\varphi$  is an  $F$ -vector space homomorphism. If  $x \in K$ , we have

$$T_\sigma T_\alpha(x) = T_\sigma(\alpha x) = \sigma(\alpha x) = \sigma(\alpha) \sigma(x) = T_{\sigma(\alpha)} T_\sigma,$$

so  $T_\sigma T_\alpha = T_{\sigma(\alpha)} T_\sigma$  as linear transformations on  $K$ . It then follows from  $u_\sigma u_\tau = u_{\sigma\tau}$  that

$$\begin{aligned}\varphi((\alpha u_\sigma)(\beta u_\tau)) &= \varphi(\alpha \sigma(\beta) u_{\sigma\tau}) = T_{\alpha\sigma(\beta)} T_{\sigma\tau} = T_\alpha T_{\sigma(\beta)} T_\sigma T_\tau \\ &= T_\alpha T_\sigma T_\beta T_\tau = \varphi(\alpha u_\sigma) \varphi(\beta u_\tau)\end{aligned}$$

which shows that  $\varphi$  is an  $F$ -algebra homomorphism from  $B_0$  to  $M_n(F)$ . Since  $\ker \varphi$  is an ideal in  $B_0$  and  $\varphi \neq 0$ , it follows from Proposition 40 that  $\ker \varphi = 0$  and  $\varphi$  is an injection. Since both  $B_0$  and  $M_n(F)$  have dimension  $n^2$  as vector spaces over  $F$ , it follows that  $\varphi$  is an  $F$ -algebra isomorphism, proving the proposition.

### Example

If  $K = \mathbb{C}$  and  $F = \mathbb{R}$ , then  $G = \text{Gal}(\mathbb{C}/\mathbb{R})$  is of order 2 and generated by complex conjugation  $\tau$ . We have  $|H^2(G, \mathbb{C}^\times)| = 2$ . The central simple  $\mathbb{R}$ -algebra  $B_0$  corresponding to the trivial class is  $\mathbb{C}u_1 \oplus \mathbb{C}u_\tau$  with  $u_\tau(a + bi) = (a - bi)u_\tau$  and  $u_\tau^2 = u_1$ . This is isomorphic to the matrix algebra  $M_2(\mathbb{R})$  under the map

$$\varphi((a + bi)u_1 + (c + di)u_\tau) = aI + bT_i + cT_\tau + dT_i T_\tau = \begin{pmatrix} a + c & -b + d \\ b + d & a - c \end{pmatrix}.$$

A normalized cocycle  $f$  representing the nontrivial cohomology class is defined by the values  $a_{1,1} = a_{1,\tau} = a_{\tau,1} = 1$  and  $a_{\tau,\tau} = -1$ . The corresponding central simple  $\mathbb{R}$ -algebra  $B_f$  is given by  $\mathbb{C}v_1 \oplus \mathbb{C}v_\tau$ . The element  $v_1$  is the identity of  $B_f$ , and we have the relations  $v_\tau(a + bi) = (a - bi)v_\tau$  and  $v_\tau^2 = -v_1$ . Letting  $v_1 = 1$  and  $v_\tau = j$  we see that  $B_f$  is isomorphic as an  $\mathbb{R}$ -algebra to the real Hamilton Quaternions  $\mathbb{R} + \mathbb{R}i + \mathbb{R}j + \mathbb{R}k$ .

There is a rich theory of simple algebras and we mention without proof the following results. Let  $A$  be a central simple  $F$ -algebra of finite dimension over  $F$ .

- I. If  $F \subseteq B \subseteq A$  where  $B$  is a simple  $F$ -algebra define the *centralizer*  $B^c$  of  $B$  in  $A$  to be the elements of  $A$  that commute with all the elements of  $B$ . Define the *opposite algebra*  $B^{opp}$  to be the set  $B$  with opposite multiplication, i.e., the product  $b_1 b_2$  in  $B^{opp}$  is given by the product  $b_2 b_1$  in  $B$ . Both  $B^c$  and  $B^{opp}$  are simple  $F$ -algebras and we have
  - a.  $(\dim_F B)(\dim_F B^c) = \dim_F A$
  - b.  $A \otimes_F B^{opp} \cong M_r(B^c)$  as  $F$ -algebras, where  $r = \dim_F B$
  - c.  $B \otimes_F B^c \cong A$  if  $B$  is a central simple  $F$ -algebra.
- II. If  $A'$  is an Artinian (satisfies D.C.C. on left ideals) simple  $F$ -algebra, then  $A \otimes_F A'$  is an Artinian simple  $F$ -algebra with center  $(A')^c$ .
- III. We have  $A \cong M_r(\Delta)$  for some division ring  $\Delta$  whose center is  $F$  and some integer  $r \geq 1$ . The division ring  $\Delta$  and  $r$  are uniquely determined by  $A$ . The same statement holds for any Artinian simple  $F$ -algebra.

The last result is part of Wedderburn's Theorem described in greater detail in the following chapter.

**Definition.** If  $A$  is a central simple  $F$ -algebra then a field  $L$  containing  $F$  is said to *split*  $A$  if  $A \otimes_F L \cong M_m(L)$  for some  $m \geq 1$ .

It follows from (II) that every maximal commutative subalgebra of  $\Delta$  is a field  $E$  with  $E = E^c = E^{opp}$ ; if  $[E : F] = m$  we obtain  $\dim_F \Delta = m^2$ . Applying (II) to  $A = \Delta$  and  $B = E$  we also see that  $\Delta \otimes_F E \cong M_m(E)$ . It can also be shown that a maximal subfield  $E$  of the central simple  $F$ -algebra  $A$  also satisfies  $E = E^c = E^{opp}$  and so again by (II) it follows that  $A \otimes_F E \cong M_r(E)$  ( $r^2 = \dim_F A$ ).

If  $A = M_r(\Delta)$  then the field  $L$  splits  $A$  if and only if  $L$  splits  $\Delta$ , as follows. If  $\Delta \otimes_F L \cong M_n(L)$  then

$$A \otimes_F L \cong M_r(\Delta) \otimes_F L \cong M_r(\Delta \otimes_F L) \cong M_r(M_n(L)) \cong M_{rn}(L).$$

Conversely if  $A \otimes_F L \cong M_n(L)$  then

$$M_n(L) \cong M_r(\Delta) \otimes_F L \cong M_r(\Delta \otimes_F L).$$

By (II) and (III),  $\Delta \otimes_F L \cong M_s(\Delta')$  for some division ring  $\Delta'$ . Together with the previous isomorphism, the uniqueness statement in (III) shows that  $\Delta' \cong L$  and then the isomorphism  $\Delta \otimes_F L \cong M_s(L)$  shows that  $L$  splits  $\Delta$ .

We see from the discussion above that a maximal commutative subfield of  $\Delta$  splits both  $\Delta$  and  $A \cong M_r(\Delta)$  for any  $r \geq 1$ . It is not too difficult to show from this that every central simple  $F$ -algebra of finite dimension over  $F$  can be split by a finite Galois extension of  $F$ .

Applying (I) by taking  $A$  to be the crossed product algebra  $B_f$  and taking  $B = K$  shows that  $K = K^c = K^{opp}$  and  $B_f \otimes_F K \cong M_n(K)$ . In particular, the crossed product algebras  $B_f$  are always split by  $K$ .

### Example

In the example of the Hamilton Quaternions above we have  $B_f \otimes_{\mathbb{R}} \mathbb{C} \cong M_2(\mathbb{C})$ . We have  $B_f \otimes_{\mathbb{R}} \mathbb{C} = \mathbb{C} + \mathbb{C}i + \mathbb{C}j + \mathbb{C}k$  and an explicit isomorphism  $\varphi$  to  $M_2(\mathbb{C})$  is given by

$$\varphi(i) = \begin{pmatrix} \sqrt{-1} & 0 \\ 0 & -\sqrt{-1} \end{pmatrix} \quad \varphi(j) = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$$

and extending  $\mathbb{C}$ -linearly.

By (III) every central simple  $F$ -algebra  $A$  is isomorphic as an  $F$ -algebra to  $M_r(\Delta)$  for some division ring  $\Delta$  uniquely determined up to  $F$ -isomorphism, called the *division ring part* of  $A$ .

**Definition.** Two central simple  $F$ -algebras  $A$  and  $B$  are *similar* if  $A \cong M_r(\Delta)$  and  $B \cong M_s(\Delta)$  for the same division ring  $\Delta$ , i.e., if  $A$  and  $B$  have the same division ring parts.

Let  $[A]$  denote the similarity class of  $A$ . By (II), if  $A$  and  $B$  are central simple  $F$ -algebras then  $A \otimes_F B$  is again a central simple  $F$ -algebra, so we may define a multiplication on similarity classes by  $[A][B] = [A \otimes_F B]$ . The class  $[F]$  is an identity for this multiplication and associativity of the tensor product shows that the multiplication is associative. By (Ib) applied with  $B = A$  (so then  $B^c = F$  since  $A$  is central) we have  $[A][A^{opp}] = [F]$ , so inverses exist with this multiplication.

**Definition.** The group of similarity classes of central simple  $F$ -algebras with multiplication  $[A][B] = [A \otimes_F B]$  is called the *Brauer group* of  $F$  and is denoted  $Br(F)$ .

If  $L$  is any extension field of  $F$  then by (II) the algebra  $A \otimes_F L$  is a central simple  $L$ -algebra. It is easy to check that the map  $[A] \rightarrow [A \otimes_F L]$  is a well defined homomorphism from  $Br(F)$  to  $Br(L)$ . The kernel of this homomorphism consists of the classes of the algebras  $A$  with  $A \otimes_F L \cong M_m(L)$  for some  $m \geq 1$ , i.e., the algebras  $A$  that are split by  $L$ .

**Definition.** If  $L/F$  is a field extension then the *relative Brauer group*  $Br(L/F)$  is the group of similarity classes of central simple  $F$ -algebras that are split by  $L$ . Equivalently,  $Br(L/F)$  is the kernel of the homomorphism  $[A] \rightarrow [A \otimes_F L]$  from  $Br(F)$  to  $Br(L)$ .

The following theorem summarizes some major results in this area and shows the fundamental connection between Brauer groups and the crossed product algebras constructed above.

**Theorem 42.** Suppose  $K/F$  is a Galois extension of degree  $n$  with  $G = \text{Gal}(K/F)$ .

- (1) The central simple  $F$ -algebra  $A$  with  $\dim_F A = n^2$  is split by  $K$  if and only if  $A \otimes_F K \cong M_n(K)$  if and only if  $A$  is isomorphic to a crossed product algebra  $B_f$  as in (39) and (40).
- (2) There is a bijection between the  $F$ -isomorphism classes of central simple  $F$ -algebras  $A$  with  $A \otimes_F K \cong M_n(K)$  and the elements of  $H^2(G, K^\times)$ . Under this bijection the class  $c \in H^2(G, K^\times)$  containing the normalized cocycle  $f$  corresponds to the isomorphism class of the crossed product algebra  $B_f$  defined in (39) and (40), and the trivial cohomology class corresponds to  $M_n(F)$ .
- (3) Every central simple  $F$ -algebra of finite dimension over  $F$  and split by  $K$  is similar to one of dimension  $n^2$  split by  $K$ . The bijection in (2) also establishes a bijection between  $Br(K/F)$  and  $H^2(G, K^\times)$  which is also an isomorphism of groups.
- (4) There is a bijection between the collection of  $F$ -isomorphism classes of central simple division algebras over  $F$  that are split by  $K$  and  $H^2(G, K^\times)$ .

As previously mentioned, every central simple  $F$ -algebra of finite dimension over  $F$  can be split by some finite Galois extension of  $F$ , and it follows that

$$Br(F) = \bigcup_K Br(K/F)$$

where the union is over all finite Galois extensions of  $F$ . It follows that there is a bijection between  $Br(F)$  and  $H^2(\text{Gal}(F^s/F), (F^s)^\times)$  where  $F^s$  denotes a separable algebraic closure of  $F$ . Here  $\text{Gal}(F^s/F)$  is considered as a profinite group and the cohomology group refers to continuous Galois cohomology.

One consequence of this result and Theorem 42 is that a full set of representatives for the  $F$ -isomorphism classes of central simple division algebras  $\Delta$  over  $F$  can be obtained from the division algebra parts of the crossed product algebras for finite Galois extensions of  $F$ . Those division algebras that are split over  $K$  occur for the crossed product algebras for  $K/F$ .

### Example

Since  $H^2(\text{Gal}(\mathbb{F}_{q^d}/\mathbb{F}_q), \mathbb{F}_{q^d}^\times) = 0$  (cf. Exercise 10), we have  $\text{Br}(\mathbb{F}_{q^d}/\mathbb{F}_q) = 0$  and hence also  $\text{Br}(\mathbb{F}_q) = 0$ . As a consequence, every finite division algebra is a field (cf. Exercise 13 in Section 13.6 for a direct proof), and every finite central simple algebra  $\mathbb{F}_q$ -algebra is isomorphic to a full matrix ring  $M_r(\mathbb{F}_q)$ .

## EXERCISES

1. Let  $A = \{1, a, b, c\}$  be the Klein 4-group and let  $G = \langle g \rangle$  be the cyclic group of order 2 acting trivially on  $A$ .
  - (a) Prove that  $|C^2(G, A)| = 2^8$ .
  - (b) Show that coboundaries are constant functions, and deduce that  $|B^2(G, A)| = 4$ .
  - (c) Use the cocycle condition to show that  $|Z^2(G, A)| \leq 2^4$ .
  - (d) If  $E = Z_4 \times Z_2 = \langle x \rangle \times \langle y \rangle$ , prove that the extensions  $1 \rightarrow A \xrightarrow{\iota_1} E \xrightarrow{\pi} G \rightarrow 1$  defined by  $\pi(x) = g$ ,  $\pi(y) = 1$  and  $\iota_1(a) = x^2$ ,  $\iota_1(b) = y$  (respectively,  $\iota_2(b) = x^2$ ,  $\iota_2(a) = y$ , and  $\iota_3(c) = x^2$ ,  $\iota_3(a) = y$ ), together with the split extension  $Z_2 \times Z_2 \times Z_2$  give 4 inequivalent extensions of  $Z_2$  by the Klein 4-group. Deduce that  $H^2(G, A)$  has order 4 by explicitly exhibiting the corresponding cocycles.
2. Let  $A = \mathbb{Z}/4\mathbb{Z}$  and let  $G$  be the cyclic group of order 2 acting trivially on  $A$ .
  - (a) Prove that  $|C^2(G, A)| = 2^8$ .
  - (b) Use the coboundary condition to show that  $|B^2(G, A)| = 2^3$ .
  - (c) Use the cocycle condition to show that  $|Z^2(G, A)| \leq 2^4$ .
  - (d) Show that  $|H^2(G, A)| = 2$  by exhibiting two inequivalent extensions of  $G$  by  $A$  and their corresponding cocycles.
3. Let  $A = \mathbb{Z}/4\mathbb{Z}$  and let  $G$  be the cyclic group of order 2 acting by inversion on  $A$ .
  - (a) Show that there are four coboundaries and that only the zero coboundary is normalized.
  - (b) Prove by a direct computation of cocycle and coboundary groups that  $|H^2(G, A)| = 2$ .
  - (c) Exhibit two distinct cohomology classes and their corresponding extension groups.
  - (d) Show that for a given extension of  $G$  by  $A$  with extension group isomorphic to  $D_8$  there are four normalized sections, all of which have the zero 2-cocycle as their factor set.
  - (e) Show that for a given extension of  $G$  by  $A$  with extension group isomorphic to  $Q_8$  there are sixteen sections, four of which are normalized, and all of the latter have the same factor set.
4. For a non-normalized 2-cocycle  $f$  one defines the extension group  $E_f$  on the set  $A \times G$  by the same binary operation in equation (34). Verify two of the group axioms in this case by showing that identity is now  $(-f(1, 1), 1)$  and inverses are given by
 
$$(a, x)^{-1} = (-x^{-1} \cdot a - f(x^{-1}, x) - f(1, 1), x^{-1}).$$

(Verification of the associative law is essentially the same as for normalized 2-cocycles.) Prove also that the set  $A^{**} = \{(a - f(1, 1), 1) \mid a \in A\}$  is a subgroup of  $E_f$  and the map  $\iota^{**} : a \mapsto (a - f(1, 1), 1)$  is an isomorphism from  $A$  to  $A^{**}$ . Show that this extension  $E_f$ , with the injection  $\iota^{**}$  and the usual projection map  $\pi^*$  onto  $G$ , is equivalent to an extension derived from a normalized cocycle in the same class as  $f$ .

5. Show that the set of equivalences of a given extension  $1 \rightarrow A \xrightarrow{\iota} E \xrightarrow{\pi} G \rightarrow 1$  with itself form a group under composition, and that this group is isomorphic to the stability group

$\text{Stab}(1 \trianglelefteq \iota(A) \trianglelefteq E)$ . (Thus Proposition 31 implies  $Z^1(G, A)$  is the group of equivalences of the extension with itself).

6. (*Gaschütz's Theorem*) Let  $p$  be a prime, let  $A$  be an abelian normal  $p$ -subgroup of a finite group  $G$ , and let  $P$  be a Sylow  $p$ -subgroup of  $G$ . Prove that  $G$  is a split extension of  $G/A$  by  $A$  if and only if  $P$  is a split extension of  $P/A$  by  $A$ . (Note that  $A \leq P$  by Exercise 37 in Section 4.5). [Use Sylow's Theorem to show if  $G$  splits over  $A$  then so too does  $P$ . Conversely, show that a normalized 2-cocycle associated to the extension of  $P/A$  by  $A$  via Theorem 36 is the image of a normalized 2-cocycle in  $H^2(G/A, A)$  under the restriction homomorphism  $\text{Res} : H^2(G/A, A) \rightarrow H^2(P/A, A)$ . Then use Proposition 26 and the fact that multiplication by  $|G : P|$  is an automorphism of  $A$ .]
7. (a) Prove that  $H^2(A_4, \mathbb{Z}/2\mathbb{Z}) \neq 0$  by exhibiting a nonsplit extension of  $A_4$  by a cyclic group of order 2. [See Exercise 11, Section 4.5.]  
 (b) Prove that  $H^2(A_5, \mathbb{Z}/2\mathbb{Z}) \neq 0$  by showing that  $SL_2(\mathbb{F}_5)$  is a nonsplit extension of  $A_5$  by a cyclic group of order 2. [Use Propositions 21 and 23 in Section 4.5.]
8. The *Schur multiplier* of a finite group  $G$  is defined as the group  $H^2(G, \mathbb{C}^\times)$ , where the multiplicative group  $\mathbb{C}^\times$  of complex numbers is a trivial  $G$ -module. Prove that the Schur multiplier is a finite group. [Show that every cohomology class contains a cocycle whose values lie in the  $n^{\text{th}}$  roots of unity, where  $n = |G|$ , as follows: If  $f$  is any cocycle then by Corollary 27,  $f^n \in B^2(G, \mathbb{C}^\times)$ . Define  $k \in C^2(G, \mathbb{C}^\times)$  by  $k(g_1, g_2) = f(g_1, g_2)^{1/n}$  (take any  $n^{\text{th}}$  roots). Show that  $k \in B^2(G, \mathbb{C}^\times)$  and  $fk^{-1}$  takes values in the group of  $n^{\text{th}}$  roots of 1.]
9. Use the classification of the extensions of the Klein 4-group by  $Z_2$  in the example following Theorem 39 to prove the following (in the notation of that example):  
 (a) There is an (outer) automorphism of  $Z_4 \times Z_2$  which interchanges the cosets  $Ax$  and  $Axy$  and fixes the coset  $Ay$ .  
 (b) There is an outer automorphism of  $D_8$  which interchanges the cosets  $As$  and  $Asr$  and fixes the coset  $Ar$ .
10. Suppose  $\mathbb{F}_q$  is a finite field with  $G = \text{Gal}(\mathbb{F}_{q^d}/\mathbb{F}_q) = \langle \sigma_q \rangle$  where  $\sigma_q$  is the Frobenius automorphism, and let  $N$  be the usual norm element for the cyclic group  $G$ .  
 (a) Use Hilbert's Theorem 90 to prove that  $|N(\mathbb{F}_{q^d}^\times)| = (q^d - 1)/(q - 1)$ , and deduce that the norm map from  $\mathbb{F}_{q^d}$  to  $\mathbb{F}_q$  is surjective.  
 (b) Prove that  $H^n(G, \mathbb{F}_{q^d}^\times) = 0$  for all  $n \geq 1$ .

# Part VI

## INTRODUCTION TO THE REPRESENTATION THEORY OF FINITE GROUPS

The final two chapters are an introduction to the representation theory of finite groups together with some applications. We have already seen in Part I how actions of groups on sets, namely permutation representations, are a fundamental tool for unravelling the structure of groups. Cayley's Theorem and Sylow's Theorem as well as many of the results and applications in Sections 6.1 and 6.2 are based on groups acting on sets. The chapter on Galois Theory developed one of the most beautiful correspondences in mathematics where the action of a group as automorphisms of a field gives rise to a correspondence between the lattice of subgroups of the Galois group and the lattice of subfields of a Galois extension of fields. In these final two chapters we study groups acting as linear transformations on vector spaces. We shall be primarily interested in utilizing these linear actions to provide information about the groups themselves.

In Part III we saw that modules are the “representation objects” for rings in the sense that the axioms for an  $R$ -module specify a “ring action” of  $R$  on some abelian group  $M$  which preserves the abelian group structure of  $M$ . In the case where  $M$  was an  $F[x]$ -module,  $x$  acted as a linear transformation from the vector space  $M$  to itself. In Chapter 12 the classification of finitely generated modules over Principal Ideal Domains gave us a great deal of information about these linear transformations of  $M$  (e.g., canonical forms). In Chapter 16 we used the ideal structure in Dedekind Domains to generalize the results of Chapter 12 to the classification of finitely generated modules over such domains. In this part we follow a process similar to the study of  $F[x]$ -modules, replacing the polynomial ring with the group ring  $FG$  of  $G$  and classifying all finitely generated  $FG$ -modules for certain fields  $F$  (Wedderburn's Theorem). We then use this classification to derive some results about finite groups such as Burnside's Theorem on the solvability of groups of order  $p^aq^b$  in Chapter 19.

# Representation Theory and Character Theory

## 18.1 LINEAR ACTIONS AND MODULES OVER GROUP RINGS

For the remainder of the book the groups we consider will be finite groups, unless explicitly mentioned otherwise. Throughout this section  $F$  is a field and  $G$  is a finite group. We first introduce the basic terminology. Recall that if  $V$  is a vector space over  $F$ , then  $GL(V)$  is the group of nonsingular linear transformations from  $V$  to itself (under composition), and if  $n \in \mathbb{Z}^+$ , then  $GL_n(F)$  is the group of invertible  $n \times n$  matrices with entries from  $F$  (under matrix multiplication).

**Definition.** Let  $G$  be a finite group, let  $F$  be a field and let  $V$  be a vector space over  $F$ .

- (1) A *linear representation* of  $G$  is any homomorphism from  $G$  into  $GL(V)$ . The *degree* of the representation is the dimension of  $V$ .
- (2) Let  $n \in \mathbb{Z}^+$ . A *matrix representation* of  $G$  is any homomorphism from  $G$  into  $GL_n(F)$ .
- (3) A linear or matrix representation is *faithful* if it is injective.
- (4) The *group ring* of  $G$  over  $F$  is the set of all formal sums of the form

$$\sum_{g \in G} \alpha_g g, \quad \alpha_g \in F$$

with componentwise addition and multiplication  $(\alpha g)(\beta h) = (\alpha\beta)(gh)$  (where  $\alpha$  and  $\beta$  are multiplied in  $F$  and  $gh$  is the product in  $G$ ) extended to sums via the distributive law (cf. Section 7.2).

Unless we are specifically discussing permutation representations the term “representation” will always mean “linear representation.” When we wish to emphasize the field  $F$  we shall say  $F$ -representation, or representation of  $G$  on  $V$  over  $F$ .

Recall that if  $V$  is a finite dimensional vector space of dimension  $n$ , then by fixing a basis of  $V$  we obtain an isomorphism  $GL(V) \cong GL_n(F)$ . In this way any linear representation of  $G$  on a finite dimensional vector space gives a matrix representation and vice versa. For the most part our linear representations will be of finite degree and we shall pass freely between linear representations and matrix representations (specifying a

basis when we wish to give an explicit correspondence between the two). Furthermore, given a linear representation  $\varphi : G \rightarrow GL(V)$  of finite degree, a corresponding matrix representation provides numerical invariants (such as the determinant of  $\varphi(g)$  for  $g \in G$ ) which are independent of the choice of basis giving the isomorphism between  $GL(V)$  and  $GL_n(F)$ . The exploitation of such invariants will be fundamental to our development.

Before giving examples of representations we recall the group ring  $FG$  in greater detail (group rings were introduced in Section 7.2, and some notation and examples were discussed in that section). Suppose the elements of  $G$  are  $g_1, g_2, \dots, g_n$ . Each element of  $FG$  is of the form

$$\sum_{i=1}^n \alpha_i g_i, \quad \alpha_i \in F.$$

Two formal sums<sup>1</sup> are equal if and only if all corresponding coefficients of group elements are equal. Addition and multiplication in  $FG$  are defined as follows:

$$\begin{aligned} \sum_{i=1}^n \alpha_i g_i + \sum_{i=1}^n \beta_i g_i &= \sum_{i=1}^n (\alpha_i + \beta_i) g_i \\ \left( \sum_{i=1}^n \alpha_i g_i \right) \left( \sum_{i=1}^n \beta_i g_i \right) &= \sum_{k=1}^n \left( \sum_{\substack{i,j \\ g_i g_j = g_k}} \alpha_i \beta_j \right) g_k \end{aligned}$$

where addition and multiplication of the coefficients  $\alpha_i$  and  $\beta_i$  is performed in  $F$ . Note that by definition of multiplication,

$FG$  is a commutative ring if and only if  $G$  is an abelian group.

The group  $G$  appears in  $FG$  (identifying  $g_i$  with  $1g_i$ ) and the field  $F$  appears in  $FG$  (identifying  $\beta$  with  $\beta g_1$ , where  $g_1$  is the identity of  $G$ ). Under these identifications

$$\beta \left( \sum_{i=1}^n \alpha_i g_i \right) = \sum_{i=1}^n (\beta \alpha_i) g_i, \quad \text{for all } \beta \in F.$$

In this way

$FG$  is a vector space over  $F$  with the elements of  $G$  as a basis.

In particular,  $FG$  is a vector space over  $F$  of dimension equal to  $|G|$ . The elements of  $F$  commute with all elements of  $FG$ , i.e.,  $F$  is in the *center* of  $FG$ . When we wish to emphasize the latter two properties we shall say that  $FG$  is an  *$F$ -algebra* (in general, an  $F$ -algebra is a ring  $R$  which contains  $F$  in its center, so  $R$  is both a ring and an  $F$ -vector space).

Note that the operations in  $FG$  are similar to those in the  $F$ -algebra  $F[x]$  (although  $F[x]$  is infinite dimensional over  $F$ ). In some works  $FG$  is denoted by  $F[G]$ , although the latter notation is currently less prevalent.

---

<sup>1</sup>The formal sum displayed above is a way of writing the function from  $G$  to  $F$  which takes the value  $\alpha_i$  on the group element  $g_i$ . This same “formality” was used in the construction of free modules (see Theorem 6 in Section 10.3).

## Examples

(1) If  $G = \langle g \rangle$  is cyclic of order  $n \in \mathbb{Z}^+$ , then the elements of  $FG$  are of the form

$$\sum_{i=0}^{n-1} \alpha_i g^i.$$

The map  $F[x] \rightarrow F\langle g \rangle$  which sends  $x^k$  to  $g^k$  for all  $k \geq 0$  extends by  $F$ -linearity to a surjective ring homomorphism with kernel equal to the ideal generated by  $x^n - 1$ . Thus

$$F\langle g \rangle \cong F[x]/(x^n - 1).$$

This is an isomorphism of  $F$ -algebras, i.e., is a ring isomorphism which is  $F$ -linear.

- (2) Under the notation of the preceding example let  $r = 1 + g + g^2 + \cdots + g^{n-1}$ , so  $r$  is a nonzero element of  $F\langle g \rangle$ . Note that  $rg = g + g^2 + \cdots + g^{n-1} + 1 = r$ , hence  $r(1 - g) = 0$ . Thus the ring  $F\langle g \rangle$  contains zero divisors (provided  $n > 1$ ). More generally, if  $G$  is any group of order  $> 1$ , then for any nonidentity element  $g \in G$ ,  $F\langle g \rangle$  is a subring of  $FG$ , so  $FG$  also contains zero divisors.
- (3) Let  $G = S_3$  and  $F = \mathbb{Q}$ . The elements  $r = 5(12) - 7(123)$  and  $s = -4(123) + 12(132)$  are typical members of  $\mathbb{Q}S_3$ . Their sum and product are seen to be

$$r + s = 5(12) - 11(123) + 12(132)$$

$$rs = -20(23) + 28(132) + 60(13) - 84$$

(recall that products (compositions) of permutations are computed from right to left). An explicit example of a sum and product of two elements in the group ring  $\mathbb{Q}D_8$  appears in Section 7.2.

Before giving specific examples of representations we discuss the correspondence between representations of  $G$  and  $FG$ -modules (after which we can simultaneously give examples of both). This discussion closely parallels the treatment of  $F[x]$ -modules in Section 10.1.

Suppose first that  $\varphi : G \rightarrow GL(V)$  is a representation of  $G$  on the vector space  $V$  over  $F$ . As above, write  $G = \{g_1, \dots, g_n\}$ , so for each  $i \in \{1, \dots, n\}$ ,  $\varphi(g_i)$  is a linear transformation from  $V$  to itself. Make  $V$  into an  $FG$ -module by defining the action of a ring element on an element of  $V$  as follows:

$$\left( \sum_{i=1}^n \alpha_i g_i \right) \cdot v = \sum_{i=1}^n \alpha_i \varphi(g_i)(v), \quad \text{for all } \sum_{i=1}^n \alpha_i g_i \in FG, \ v \in V.$$

We verify a special case of axiom 2(b) of a module (see Section 10.1) which shows precisely where the fact that  $\varphi$  is a group homomorphism is needed:

$$\begin{aligned} (g_i g_j) \cdot v &= \varphi(g_i g_j)(v) && \text{(by definition of the action)} \\ &= (\varphi(g_i) \circ \varphi(g_j))(v) && \text{(since } \varphi \text{ is a group homomorphism)} \\ &= \varphi(g_i)(\varphi(g_j)(v)) && \text{(by definition of a composition of linear} \\ &&& \text{transformations)} \\ &= g_i \cdot (g_j \cdot v) && \text{(by definition of the action).} \end{aligned}$$

This argument extends by linearity to arbitrary elements of  $FG$  to prove that axiom 2(b) of a module holds in general. It is an exercise to check that the remaining module axioms hold.

Note that  $F$  is a subring of  $FG$  and the action of the field element  $\alpha$  on a vector is the same as the action of the ring element  $\alpha 1$  on a vector i.e., the  $FG$ -module action extends the  $F$  action on  $V$ .

Suppose now that conversely we are given an  $FG$ -module  $V$ . We obtain an associated vector space over  $F$  and representation of  $G$  as follows. Since  $V$  is an  $FG$ -module, it is an  $F$ -module, i.e., it is a vector space over  $F$ . Also, for each  $g \in G$  we obtain a map from  $V$  to  $V$ , denoted by  $\varphi(g)$ , defined by

$$\varphi(g)(v) = g \cdot v \quad \text{for all } v \in V,$$

where  $g \cdot v$  is the given action of the ring element  $g$  on the element  $v$  of  $V$ . Since the elements of  $F$  commute with each  $g \in G$  it follows by the axioms for a module that for all  $v, w \in V$  and all  $\alpha, \beta \in F$  we have

$$\begin{aligned} \varphi(g)(\alpha v + \beta w) &= g \cdot (\alpha v + \beta w) \\ &= g \cdot (\alpha v) + g \cdot (\beta w) \\ &= \alpha(g \cdot v) + \beta(g \cdot w) \\ &= \alpha\varphi(g)(v) + \beta\varphi(g)(w), \end{aligned}$$

that is, for each  $g \in G$ ,  $\varphi(g)$  is a linear transformation. Furthermore, it follows by axiom 2(b) of a module that

$$\varphi(g_i g_j)(v) = (\varphi(g_i) \circ \varphi(g_j))(v)$$

(this is essentially the calculation above with the steps reversed). This proves that  $\varphi$  is a group homomorphism (in particular,  $\varphi(g^{-1}) = \varphi(g)^{-1}$ , so every element of  $G$  maps to a nonsingular linear transformation, i.e.,  $\varphi : G \rightarrow GL(V)$ ).

This discussion shows there is a bijection between  $FG$ -modules and pairs  $(V, \varphi)$ :

$$\left\{ \begin{array}{l} V \text{ an } FG\text{-module} \end{array} \right\} \longleftrightarrow \left\{ \begin{array}{c} V \text{ a vector space over } F \\ \text{and} \\ \varphi : G \rightarrow GL(V) \text{ a representation} \end{array} \right\}.$$

Giving a representation  $\varphi : G \rightarrow GL(V)$  on a vector space  $V$  over  $F$  is therefore equivalent to giving an  $FG$ -module  $V$ . Under this correspondence we shall say that the module  $V$  *affords* the representation  $\varphi$  of  $G$ .

Recall from Section 10.1 that if a vector space  $M$  is made into an  $F[x]$ -module via the linear transformation  $T$ , then the  $F[x]$ -submodules of  $M$  are precisely the  $T$ -stable subspaces of  $M$ . In the current situation if  $V$  is an  $FG$ -module affording the representation  $\varphi$ , then a subspace  $U$  of  $V$  is called  *$G$ -invariant* or  *$G$ -stable* if  $g \cdot u \in U$  for all  $g \in G$  and all  $u \in U$  (i.e., if  $\varphi(g)(u) \in U$  for all  $g \in G$  and all  $u \in U$ ). It follows easily that

*the  $FG$ -submodules of  $V$  are precisely the  $G$ -stable subspaces of  $V$ .*

## Examples

- (1) Let  $V$  be a 1-dimensional vector space over  $F$  and make  $V$  into an  $FG$ -module by letting  $gv = v$  for all  $g \in G$  and  $v \in V$ . This module affords the representation  $\varphi : G \rightarrow GL(V)$  defined by  $\varphi(g) = I$  = the identity linear transformation, for all  $g \in G$ . The corresponding matrix representation (with respect to any basis of  $V$ ) is the homomorphism of  $G$  into  $GL_1(F)$  which sends every group element to the  $1 \times 1$  identity matrix. We shall henceforth refer to this as the *trivial representation* of  $G$ . The trivial representation has degree 1 and if  $|G| > 1$ , it is not faithful.
- (2) Let  $V = FG$  and consider this ring as a left module over itself. Then  $V$  affords a representation of  $G$  of degree equal to  $|G|$ . If we take the elements of  $G$  as a basis of  $V$ , then each  $g \in G$  permutes these basis elements under the left regular permutation representation:
 
$$g \cdot g_i = gg_i.$$

With respect to this basis of  $V$  the matrix of the group element  $g$  has a 1 in row  $i$  and column  $j$  if  $gg_j = g_i$ , and has 0's in all other positions. This (linear or matrix) representation is called the *regular representation* of  $G$ . Note that each nonidentity element of  $G$  induces a nonidentity permutation on the basis of  $V$  so the regular representation is always faithful.

- (3) Let  $n \in \mathbb{Z}^+$ , let  $G = S_n$  and let  $V$  be an  $n$ -dimensional vector space over  $F$  with basis  $e_1, e_2, \dots, e_n$ . Let  $S_n$  act on  $V$  by defining for each  $\sigma \in S_n$

$$\sigma \cdot e_i = e_{\sigma(i)}, \quad 1 \leq i \leq n$$

i.e.,  $\sigma$  acts by permuting the subscripts of the basis elements. This provides an (injective) homomorphism of  $S_n$  into  $GL(V)$  (i.e., a faithful representation of  $S_n$  of degree  $n$ ), hence makes  $V$  into an  $FS_n$ -module. As in the preceding example, the matrix of  $\sigma$  with respect to the basis  $e_1, \dots, e_n$  has a 1 in row  $i$  and column  $j$  if  $\sigma \cdot e_j = e_i$  (and has 0 in all other entries). Thus  $\sigma$  has a 1 in row  $i$  and column  $j$  if  $\sigma(j) = i$ .

For an example of the ring action, consider the action of  $FS_3$  on the 3-dimensional vector space over  $F$  with basis  $e_1, e_2, e_3$ . Let  $\sigma$  be the transposition  $(1\ 2)$ , let  $\tau$  be the 3-cycle  $(1\ 2\ 3)$  and let  $r = 2\sigma - 3\tau \in FS_3$ . Then

$$\begin{aligned} r \cdot (\alpha e_1 + \beta e_2 + \gamma e_3) &= 2(\alpha e_{\sigma(1)} + \beta e_{\sigma(2)} + \gamma e_{\sigma(3)}) - 3(\alpha e_{\tau(1)} + \beta e_{\tau(2)} + \gamma e_{\tau(3)}) \\ &= 2(\alpha e_2 + \beta e_1 + \gamma e_3) - 3(\alpha e_2 + \beta e_3 + \gamma e_1) \\ &= (2\beta - 3\gamma)e_1 - \alpha e_2 + (2\gamma - 3\beta)e_3. \end{aligned}$$

- (4) If  $\psi : H \rightarrow GL(V)$  is any representation of  $H$  and  $\varphi : G \rightarrow H$  is any group homomorphism, then the composition  $\psi \circ \varphi$  is a representation of  $G$ . For example, let  $V$  be the  $FS_n$ -module of dimension  $n$  described in the preceding example. If  $\pi : G \rightarrow S_n$  is any permutation representation of  $G$ , the composition of  $\pi$  with the representation above gives a linear representation of  $G$ . In other words,  $V$  becomes an  $FG$ -module under the action

$$g \cdot e_i = e_{\pi(g)(i)}, \quad \text{for all } g \in G.$$

Note that the regular representation, (2), is just the special case of this where  $n = |G|$  and  $\pi$  is the left regular permutation representation of  $G$ .

- (5) Any homomorphism of  $G$  into the multiplicative group  $F^\times = GL_1(F)$  is a degree 1 (matrix) representation. For example, suppose  $G = \langle g \rangle \cong \mathbb{Z}_n$  is the cyclic group of order  $n$  and  $\zeta$  is a fixed  $n^{\text{th}}$  root of 1 in  $F$ . Let  $g^i \mapsto \zeta^i$ , for all  $i \in \mathbb{Z}$ . This representation of  $\langle g \rangle$  is a faithful representation if and only if  $\zeta$  is a primitive  $n^{\text{th}}$  root of 1.

- (6) In many situations it is easier to specify an explicit matrix representation of a group  $G$  rather than to exhibit an  $FG$ -module. For example, recall that the dihedral group  $D_{2n}$  has the presentation

$$D_{2n} = \langle r, s \mid r^n = s^2 = 1, rs = sr^{-1} \rangle.$$

If  $R$  and  $S$  are any matrices satisfying the relations  $R^n = S^2 = I$  and  $RS = SR^{-1}$  then the map  $r \mapsto R$  and  $s \mapsto S$  extends uniquely to a homomorphism from  $D_{2n}$  to the matrix group generated by  $R$  and  $S$ , hence gives a representation of  $D_{2n}$ . An explicit example of matrices  $R, S \in M_2(\mathbb{R})$  may be obtained as follows. If a regular  $n$ -gon is drawn on the  $x, y$  plane centered at the origin with the line  $y = x$  as one of its lines of symmetry then the matrix  $R$  that rotates the plane through  $2\pi/n$  radians and the matrix  $S$  that reflects the plane about the line  $y = x$  both send this  $n$ -gon onto itself. It follows that these matrices act as symmetries of the  $n$ -gon and so satisfy the above relations. These matrices are readily computed (cf. Exercise 25, Section 1.6) and so the maps

$$r \mapsto R = \begin{pmatrix} \cos 2\pi/n & -\sin 2\pi/n \\ \sin 2\pi/n & \cos 2\pi/n \end{pmatrix} \quad \text{and} \quad s \mapsto S = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$$

extend uniquely to a (degree 2) representation of  $D_{2n}$  into  $GL_2(\mathbb{R})$ . Since the matrices  $R$  and  $S$  have orders  $n$  and 2 respectively, it follows that they generate a subgroup of  $GL_2(\mathbb{R})$  of order  $2n$  and hence this representation is faithful.

- (7) By using the usual generators and relations for the quaternion group

$$Q_8 = \langle i, j \mid i^4 = j^4 = 1, i^2 = j^2, i^{-1}ji = j^{-1} \rangle$$

one may similarly obtain (cf. Exercise 26, Section 1.6) a representation  $\varphi$  from  $Q_8$  to  $GL_2(\mathbb{C})$  defined by

$$\varphi(i) = \begin{pmatrix} \sqrt{-1} & 0 \\ 0 & -\sqrt{-1} \end{pmatrix} \quad \text{and} \quad \varphi(j) = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.$$

This representation of  $Q_8$  is faithful.

- (8) A 4-dimensional representation of the quaternion group  $Q_8$  may be obtained from the real Hamilton quaternions,  $\mathbb{H}$  (cf. Section 7.1). The group  $Q_8$  is a subgroup of the multiplicative group of units of  $\mathbb{H}$  and each of the elements of  $Q_8$  acts by left multiplication on the 4-dimensional real vector space  $\mathbb{H}$ . Since the real numbers are in the center of  $\mathbb{H}$  (i.e., since  $\mathbb{H}$  is an  $\mathbb{R}$ -algebra), left multiplication is  $\mathbb{R}$ -linear. This linear action thus gives a homomorphism from  $Q_8$  into  $GL_4(\mathbb{R})$ . One can easily write out the explicit matrices of each of the elements of  $Q_8$  with respect to the basis  $1, i, j, k$  of  $\mathbb{H}$ . For example, left multiplication by  $i$  acts by  $1 \mapsto i, i \mapsto -1, j \mapsto k$  and  $k \mapsto -j$  and left multiplication by  $j$  acts by  $1 \mapsto j, i \mapsto -k, j \mapsto -1$  and  $k \mapsto i$  so

$$i \mapsto \begin{pmatrix} 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \end{pmatrix} \quad \text{and} \quad j \mapsto \begin{pmatrix} 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{pmatrix}.$$

This representation of  $Q_8$  is also faithful.

- (9) Suppose that  $H$  is a normal subgroup of the group  $G$  and suppose that  $H$  is an elementary abelian  $p$ -group for some prime  $p$ . Then  $V = H$  is a vector space over  $\mathbb{F}_p$ , where the scalar  $a$  acts on the vector  $v$  by  $av = v^a$  (see Section 10.1). The action of each element of  $G$  by conjugation on  $V$  is  $\mathbb{F}_p$ -linear because  $gv^a g^{-1} = (gvg^{-1})^a$  and this action of  $G$  on  $V$  makes  $V$  into an  $\mathbb{F}_p G$ -module (the automorphisms of elementary abelian  $p$ -groups were discussed in Sections 4.4 and 10.1). The kernel of

this representation is the set of elements of  $G$  that commute with every element of  $H$ ,  $C_G(H)$  (which always contains the abelian group  $H$  itself). Thus the action of a group on subsets of itself often affords linear representations over finite fields. Representations of groups over finite fields are called *modular representations* and these are fundamental to the study of the internal structure of groups.

- (10) For an example of an  $FG$ -submodule, let  $G = S_n$  and let  $V$  be the  $FS_n$ -module described in Example 3. Let  $N$  be the subspace of  $V$  consisting of vectors all of whose coordinates are equal, i.e.,

$$N = \{\alpha_1 e_1 + \alpha_2 e_2 + \cdots + \alpha_n e_n \mid \alpha_1 = \alpha_2 = \cdots = \alpha_n\}$$

(this is a 1-dimensional  $S_n$ -stable subspace). Each  $\sigma \in S_n$  fixes each vector in  $N$  so the submodule  $N$  affords the trivial representation of  $S_n$ . As an exercise, one may show that if  $n \geq 3$  then  $N$  is the *unique* 1-dimensional subspace of  $V$  which is  $S_n$ -stable, i.e.,  $N$  is the unique 1-dimensional  $FS_n$ -submodule ( $N$  is called the *trace* submodule of  $FS_n$ ).

Another  $FS_n$ -submodule of  $V$  is the subspace  $I$  of all vectors whose coordinates sum to zero:

$$I = \{\alpha_1 e_1 + \alpha_2 e_2 + \cdots + \alpha_n e_n \mid \alpha_1 + \alpha_2 + \cdots + \alpha_n = 0\}.$$

Again  $I$  is an  $S_n$ -stable subspace (since each  $\sigma \in S_n$  permutes the coordinates of each vector in  $V$ , each  $\sigma$  leaves the sum of the coefficients unchanged). Since  $I$  is the kernel of the linear transformation from  $V$  onto  $F$  which sends a vector to the sum of its coefficients (called the augmentation map — cf. Section 7.3),  $I$  has dimension  $n - 1$ .

- (11) If  $V = FG$  is the regular representation of  $G$  described in Example 2 above, then  $V$  has  $FG$ -submodules of dimensions 1 and  $|G| - 1$  as in the preceding example:

$$N = \{\alpha_1 g_1 + \alpha_2 g_2 + \cdots + \alpha_n g_n \mid \alpha_1 = \alpha_2 = \cdots = \alpha_n\}$$

$$I = \{\alpha_1 g_1 + \alpha_2 g_2 + \cdots + \alpha_n g_n \mid \alpha_1 + \alpha_2 + \cdots + \alpha_n = 0\}.$$

In fact  $N$  and  $I$  are 2-sided ideals of  $FG$  (not just left ideals — note that  $N$  is in the center of  $FG$ ). The ideal  $I$  is called the *augmentation ideal* of  $FG$  and  $N$  is called the *trace ideal* of  $FG$ .

Recall that in the study of a linear transformation  $T$  of a vector space  $V$  to itself we made  $V$  into an  $F[x]$ -module (where  $x$  acted as  $T$  on  $V$ ); our goal was to decompose  $V$  into a direct sum of cyclic submodules. In this way we were able to find a basis of  $V$  for which the matrix of  $T$  with respect to this basis was in some *canonical* form. Changing the basis of  $V$  did not change the module  $V$  but changed the matrix representation of  $T$  by similarity (i.e., changed the isomorphism between  $GL(V)$  and  $GL_n(F)$ ). We introduce the analogous terminology to describe when two  $FG$ -modules are the same up to a change of basis.

**Definition.** Two representations of  $G$  are *equivalent* (or *similar*) if the  $FG$ -modules affording them are isomorphic modules. Representations which are not equivalent are called *inequivalent*.

Suppose  $\varphi : G \rightarrow GL(V)$  and  $\psi : G \rightarrow GL(W)$  are equivalent representations (here  $V$  and  $W$  must be vector spaces over the same field  $F$ ). Let  $T : V \rightarrow W$  be

an  $FG$ -module isomorphism between them. Since  $T$  is, in particular, an  $F$ -module isomorphism,  $T$  is a vector space isomorphism, so  $V$  and  $W$  must have the same dimension. Furthermore, for all  $g \in G$ ,  $v \in V$  we have  $T(g \cdot v) = g \cdot (T(v))$ , since  $T$  is an isomorphism of  $FG$ -modules. By definition of the action of ring elements this means  $T(\varphi(g)v) = \psi(g)(T(v))$ , that is

$$T \circ \varphi(g) = \psi(g) \circ T \quad \text{for all } g \in G.$$

In particular, if we identify  $V$  and  $W$  as vector spaces, then two representations  $\varphi$  and  $\psi$  of  $G$  on a vector space  $V$  are equivalent if and only if there is some  $T \in GL(V)$  such that  $T \circ \varphi(g) \circ T^{-1} = \psi(g)$  for all  $g \in G$ . This  $T$  is a *simultaneous* change of basis for all  $\varphi(g)$ ,  $g \in G$ .

In matrix terminology, two representations  $\varphi$  and  $\psi$  are equivalent if there is a fixed invertible matrix  $P$  such that

$$P\varphi(g)P^{-1} = \psi(g) \quad \text{for all } g \in G.$$

The linear transformation  $T$  or the matrix  $P$  above is said to *intertwine* the representations  $\varphi$  and  $\psi$  (it gives the “rule” for changing  $\varphi$  into  $\psi$ ).

In order to study the decomposition of an  $FG$ -module into (direct sums of) submodules we shall need some terminology. We state these definitions for arbitrary rings since we shall be discussing direct sum decompositions in greater generality in the next section.

**Definition.** Let  $R$  be a ring and let  $M$  be a nonzero  $R$ -module.

- (1) The module  $M$  is said to be *irreducible* (or *simple*) if its only submodules are  $0$  and  $M$ ; otherwise  $M$  is called *reducible*.
- (2) The module  $M$  is said to be *indecomposable* if  $M$  cannot be written as  $M_1 \oplus M_2$  for any nonzero submodules  $M_1$  and  $M_2$ ; otherwise  $M$  is called *decomposable*.
- (3) The module  $M$  is said to be *completely reducible* if it is a direct sum of irreducible submodules.
- (4) A representation is called *irreducible*, *reducible*, *indecomposable*, *decomposable* or *completely reducible* according to whether the  $FG$ -module affording it has the corresponding property.
- (5) If  $M$  is a completely reducible  $R$ -module, any direct summand of  $M$  is called a *constituent* of  $M$  (i.e.,  $N$  is a constituent of  $M$  if there is a submodule  $N'$  of  $M$  such that  $M = N \oplus N'$ ).

An irreducible module is, by definition, both indecomposable and completely reducible. We shall shortly give examples of indecomposable modules that are not irreducible.

If  $R = FG$ , an irreducible  $FG$ -module  $V$  is a nonzero  $F$ -vector space with no non-trivial, proper  $G$ -invariant subspaces. For example, if  $\dim_F V = 1$  then  $V$  is necessarily irreducible (its only subspaces are  $0$  and  $V$ ).

Suppose  $V$  is a finite dimensional  $FG$ -module and  $V$  is reducible. Let  $U$  be a  $G$ -invariant subspace. Form a basis of  $V$  by taking a basis of  $U$  and enlarging it to a

basis of  $V$ . Then for each  $g \in G$  the matrix,  $\varphi(g)$ , of  $g$  acting on  $V$  with respect to this basis is of the form

$$\varphi(g) = \begin{pmatrix} \varphi_1(g) & \psi(g) \\ 0 & \varphi_2(g) \end{pmatrix}$$

where  $\varphi_1 = \varphi|_U$  (with respect to the chosen basis of  $U$ ) and  $\varphi_2$  is the representation of  $G$  on  $V/U$  (and  $\psi$  is not necessarily a homomorphism —  $\psi(g)$  need not be a square matrix). So reducible representations are those with a corresponding matrix representation whose matrices are in block upper triangular form.

Assume further that the  $FG$ -module  $V$  is decomposable,  $V = U \oplus U'$ . Take for a basis of  $V$  the union of a basis of  $U$  and a basis of  $U'$ . With this choice of basis the matrix for each  $g \in G$  is of the form

$$\varphi(g) = \begin{pmatrix} \varphi_1(g) & 0 \\ 0 & \varphi_2(g) \end{pmatrix}$$

(i.e.,  $\psi(g) = 0$  for all  $g \in G$ ). Thus decomposable representations are those with a corresponding matrix representation whose matrices are in block diagonal form.

## Examples

- (1) As noted above, all degree 1 representations are irreducible, indecomposable and completely reducible. In particular, this applies to the trivial representation and to the representations described in Example 5 above.
- (2) If  $|G| > 1$ , the regular representation of  $G$  is reducible (the augmentation ideal and the trace ideal are proper nonzero submodules). We shall later determine the conditions under which this representation is completely reducible and how it decomposes into a direct sum.
- (3) For  $n > 1$  the  $FS_n$ -module described in Example 10 above is reducible since  $N$  and  $I$  are proper, nonzero submodules. The module  $N$  is irreducible (being 1-dimensional) and if the characteristic of the field  $F$  does not divide  $n$ , then  $I$  is also irreducible.
- (4) The degree 2 representation of the dihedral group  $D_{2n} = G$  described in Example 6 above is irreducible for  $n \geq 3$ . There are no  $G$ -invariant 1-dimensional subspaces since a rotation by  $2\pi/n$  radians sends no line in  $\mathbb{R}^2$  to itself. Similarly, the degree 2 complex representation of  $Q_8$  described in Example 7 is irreducible since the given matrix  $\varphi(i)$  has exactly two 1-dimensional eigenspaces (corresponding to its distinct eigenvalues  $\pm\sqrt{-1}$ ) and these are not invariant under the matrix  $\varphi(j)$ . The degree 4 representation  $\varphi : Q_8 \rightarrow GL_4(\mathbb{R})$  described in Example 8 can also be shown to be irreducible (see the exercises). We shall see, however, that if we view  $\varphi$  as a complex representation  $\varphi : Q_8 \rightarrow GL_4(\mathbb{C})$  (just by considering the real entries of the matrices to be complex entries) then there is a *complex* matrix  $P$  such that  $P^{-1}\varphi(g)P$  is a direct sum of  $2 \times 2$  block matrices for all  $g \in Q_8$ . Thus an irreducible representation over a field  $F$  may become reducible when the field is extended.
- (5) Let  $G = \langle g \rangle$  be cyclic of order  $n$  and assume  $F$  contains all the  $n^{\text{th}}$  roots of 1. As noted in Example 1 in the set of examples of group algebras,  $F\langle g \rangle \cong F[x]/(x^n - 1)$ . Thus the  $FG$ -modules are precisely the  $F[x]$ -modules annihilated by  $x^n - 1$ . The latter (finite dimensional) modules are described, up to equivalence, by the Jordan Canonical Form Theorem.

If the minimal polynomial of  $g$  acting on an  $F\langle g \rangle$ -module  $V$  has distinct roots in  $F$ , there is a basis of  $V$  such that  $g$  (hence all its powers) is represented by a diagonal

matrix (cf. Corollary 25, Section 12.3). In this case,  $V$  is a completely reducible  $F(g)$ -module (being a direct sum of 1-dimensional  $(g)$ -invariant subspaces). In general, the minimal polynomial of  $g$  acting on  $V$  divides  $x^n - 1$  so if  $x^n - 1$  has distinct roots in  $F$ , then  $V$  is a completely reducible  $F(g)$ -module. The polynomial  $x^n - 1$  has distinct roots in  $F$  if and only if the characteristic of  $F$  does not divide  $n$ . This gives a sufficient condition for every  $F(g)$ -module to be completely reducible.

If the minimal polynomial of  $g$  acting on  $V$  does *not* have distinct roots (so the characteristic of  $F$  does divide  $n$ ), the Jordan canonical form of  $g$  must have an elementary Jordan block of size  $> 1$ . Since every linear transformation has a unique Jordan canonical form,  $g$  cannot be represented by a diagonal matrix, i.e.,  $V$  is not completely reducible. It follows from results on cyclic modules in Section 12.3 that the (1-dimensional) eigenspace of  $g$  in any Jordan block of size  $> 1$  admits no  $(g)$ -invariant complement, i.e.,  $V$  is reducible but not completely reducible.

Specifically, let  $p$  be a prime, let  $F = \mathbb{F}_p$  and let  $g$  be of order  $p$ . Let  $V$  be the 2-dimensional space over  $\mathbb{F}_p$  with basis  $v, w$  and define an action of  $g$  on  $V$  by

$$g \cdot v = v \quad \text{and} \quad g \cdot w = v + w.$$

This endomorphism of  $V$  does have order  $p$  (in  $GL(V)$ ) and the matrix of  $g$  with respect to this basis is the elementary Jordan block

$$\varphi(g) = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}.$$

Now  $V$  is reducible ( $\text{span}\{v\}$  is a  $(g)$ -invariant subspace) but  $V$  is indecomposable (the above  $2 \times 2$  elementary Jordan matrix is not similar to a diagonal matrix).

The first fundamental result in the representation theory of finite groups shows how Example 5 generalizes to noncyclic groups.

**Theorem 1. (Maschke's Theorem)** Let  $G$  be a finite group and let  $F$  be a field whose characteristic does not divide  $|G|$ . If  $V$  is any  $FG$ -module and  $U$  is any submodule of  $V$ , then  $V$  has a submodule  $W$  such that  $V = U \oplus W$  (i.e., every submodule is a direct summand).

*Remark:* The hypothesis of Maschke's Theorem applies to any finite group when  $F$  has characteristic 0.

*Proof:* The idea of the proof of Maschke's Theorem is to produce an  $FG$ -module homomorphism

$$\pi : V \rightarrow U$$

which is a projection onto  $U$ , i.e., which satisfies the following two properties:

- (i)  $\pi(u) = u$  for all  $u \in U$
- (ii)  $\pi(\pi(v)) = \pi(v)$  for all  $v \in V$  (i.e.,  $\pi^2 = \pi$ )

(in fact (ii) is implied by (i) and the fact that  $\pi(V) \subseteq U$ ).

Suppose first that we can produce such an  $FG$ -module homomorphism and let  $W = \ker \pi$ . Since  $\pi$  is a module homomorphism,  $W$  is a submodule. We see that  $W$  is a direct sum complement to  $U$  as follows. If  $v \in U \cap W$  then by (i),  $v = \pi(v)$  whereas by definition of  $W$ ,  $\pi(v) = 0$ . This shows  $U \cap W = 0$ . To show  $V = U + W$  let  $v$  be

an arbitrary element of  $V$  and write  $v = \pi(v) + (v - \pi(v))$ . By definition,  $\pi(v) \in U$ . By property (ii) of  $\pi$ ,

$$\pi(v - \pi(v)) = \pi(v) - \pi(\pi(v)) = \pi(v) - \pi(v) = 0,$$

i.e.,  $v - \pi(v) \in W$ . This shows  $V = U + W$  and hence  $V = U \oplus W$ . To establish Maschke's Theorem it therefore suffices to find such an  $FG$ -module projection  $\pi$ .

Since  $U$  is a subspace it has a vector space direct sum complement  $W_0$  in  $V$  (take a basis  $B_1$  of  $U$ , build it up to a basis  $B$  of  $V$  and let  $W_0$  be the span of  $B - B_1$ ). Thus  $V = U \oplus W_0$  as vector spaces but  $W_0$  need not be  $G$ -stable (i.e., need not be an  $FG$ -submodule). Let  $\pi_0 : V \rightarrow U$  be the vector space projection of  $V$  onto  $U$  associated to this direct sum decomposition, i.e.,  $\pi_0$  is defined by

$$\pi_0(u + w) = u \quad \text{for all } u \in U, w \in W_0.$$

The key idea of the proof is to “average”  $\pi_0$  over  $G$  to form an  $FG$ -module projection  $\pi$ . For each  $g \in G$  define

$$g\pi_0g^{-1} : V \rightarrow U \quad \text{by} \quad g\pi_0g^{-1}(v) = g \cdot \pi_0(g^{-1} \cdot v), \quad \text{for all } v \in V$$

(here  $\cdot$  denotes the action of elements of the ring  $FG$ ). Since  $\pi_0$  maps  $V$  into  $U$  and  $U$  is stable under the action of  $g$  we have that  $g\pi_0g^{-1}$  maps  $V$  into  $U$ . Both  $g$  and  $g^{-1}$  act as  $F$ -linear transformations, so  $g\pi_0g^{-1}$  is a linear transformation. Furthermore, if  $u$  is in the  $G$ -stable space  $U$  then so is  $g^{-1}u$ , and by definition of  $\pi_0$  we have  $\pi_0(g^{-1}u) = g^{-1}u$ . From this we obtain that for all  $g \in G$ ,

$$g\pi_0g^{-1}(u) = u \quad \text{for all } u \in U$$

(i.e.,  $g\pi_0g^{-1}$  is also a vector space projection of  $V$  onto  $U$ ).

Let  $n = |G|$  and view  $n$  as an element of  $F$  ( $n = 1 + \dots + 1$ ,  $n$  times). By hypothesis  $n$  is not zero in  $F$  and so has an inverse in  $F$ . Define

$$\pi = \frac{1}{n} \sum_{g \in G} g\pi_0g^{-1}.$$

Since  $\pi$  is a scalar multiple of a sum of linear transformations from  $V$  to  $U$ , it is also a linear transformation from  $V$  to  $U$ . Furthermore, each term in the sum defining  $\pi$  restricts to the identity map on the subspace  $U$  and so  $\pi|_U$  is  $1/n$  times the sum of  $n$  copies of the identity. These observations prove the following:

$\pi : V \rightarrow U$  is a linear transformation

$$\pi(u) = u \quad \text{for all } u \in U$$

$$\pi^2(v) = \pi(v) \quad \text{for all } v \in V.$$

It remains to show that  $\pi$  is an  $FG$ -module homomorphism (i.e., is  $FG$ -linear). It

suffices to prove that for all  $h \in G$ ,  $\pi(hv) = h\pi(v)$ , for  $v \in V$ . In this case

$$\begin{aligned}\pi(hv) &= \frac{1}{n} \sum_{g \in G} g\pi_0(g^{-1}hv) \\ &= \frac{1}{n} \sum_{g \in G} h(h^{-1}g)\pi_0((g^{-1}h)v) \\ &= \frac{1}{n} \sum_{\substack{k=h^{-1}g \\ g \in G}} h(k\pi_0(k^{-1}v)) = h\pi(v)\end{aligned}$$

(as  $g$  runs over all elements of  $G$ , so does  $k = h^{-1}g$  and the module element  $h$  may be brought outside the summation by the distributive law in modules). This establishes the existence of the  $FG$ -module projection  $\pi$  and so completes the proof.

The applications of Maschke's Theorem will be to finitely generated  $FG$ -modules. Unlike the situation of  $F[x]$ -modules, however, finitely generated  $FG$ -modules are automatically finite dimensional vector spaces (the difference being that  $FG$  itself is finite dimensional, whereas  $F[x]$  is not). Let  $V$  be an  $FG$ -module. If  $V$  is a finite dimensional vector space over  $F$ , then a fortiori  $V$  is finitely generated as an  $FG$ -module (any  $F$  basis gives a set of generators over  $FG$ ). Conversely, if  $V$  is finitely generated as an  $FG$ -module, say by  $v_1, \dots, v_k$ , then one easily sees that  $V$  is spanned as a vector space by the finite set  $\{g \cdot v_i \mid g \in G, 1 \leq i \leq k\}$ . Thus

*an  $FG$ -module is finitely generated if and only if it is finite dimensional.*

**Corollary 2.** If  $G$  is a finite group and  $F$  is a field whose characteristic does not divide  $|G|$ , then every finitely generated  $FG$ -module is completely reducible (equivalently, every  $F$ -representation of  $G$  of finite degree is completely reducible).

*Proof:* Let  $V$  be a finitely generated  $FG$ -module. As noted above,  $V$  is finite dimensional over  $F$ , so we may proceed by induction on its dimension. If  $V$  is irreducible, it is completely reducible and the result holds. Suppose therefore that  $V$  has a proper, nonzero  $FG$ -submodule  $U$ . By Maschke's Theorem  $U$  has an  $FG$ -submodule complement  $W$ , i.e.,  $V = U \oplus W$ . By induction, each of  $U$  and  $W$  are direct sums of irreducible submodules, hence so is  $V$ . This completes the induction.

**Corollary 3.** Let  $G$  be a finite group, let  $F$  be a field whose characteristic does not divide  $|G|$  and let  $\varphi : G \rightarrow GL(V)$  be a representation of  $G$  of finite degree. Then there is a basis of  $V$  such that for each  $g \in G$  the matrix of  $\varphi(g)$  with respect to this basis is block diagonal:

$$\begin{pmatrix} \varphi_1(g) & & & \\ & \varphi_2(g) & & \\ & & \ddots & \\ & & & \varphi_m(g) \end{pmatrix}$$

where  $\varphi_i$  is an irreducible matrix representation of  $G$ ,  $1 \leq i \leq m$ .

*Proof:* By Corollary 2 we may write  $V = U_1 \oplus U_2 \oplus \cdots \oplus U_m$ , where  $U_i$  is an irreducible  $FG$ -submodule of  $V$ . Let  $\mathcal{B}_i$  be a basis of  $U_i$  and let  $\mathcal{B}$  be the union of the  $\mathcal{B}_i$ 's. For each  $g \in G$ , the matrix of  $\varphi(g)$  with respect to the basis  $\mathcal{B}$  is of the form in the corollary, where  $\varphi_i(g)$  is the matrix of  $\varphi(g)|_{U_i}$  with respect to the basis  $\mathcal{B}_i$ .

The converse of Maschke's Theorem is also true. Namely, if the characteristic of  $F$  does divide  $|G|$ , then  $G$  possesses (finitely generated)  $FG$ -modules which are not completely reducible. Specifically, the regular representation (i.e., the module  $FG$  itself) is not completely reducible.

In Section 18.2 we shall discuss the question of uniqueness of the constituents in direct sum decompositions of  $FG$ -modules into irreducible submodules.

## EXERCISES

Let  $F$  be a field, let  $G$  be a finite group and let  $n \in \mathbb{Z}^+$ .

1. Prove that if  $\varphi : G \rightarrow GL(V)$  is any representation, then  $\varphi$  gives a faithful representation of  $G/\ker \varphi$ .
2. Let  $\varphi : G \rightarrow GL_n(F)$  be a matrix representation. Prove that the map  $g \mapsto \det(\varphi(g))$  is a degree 1 representation.
3. Prove that the degree 1 representations of  $G$  are in bijective correspondence with the degree 1 representations of the abelian group  $G/G'$  (where  $G'$  is the commutator subgroup of  $G$ ).
4. Let  $V$  be a (possibly infinite dimensional)  $FG$ -module ( $G$  is a finite group). Prove that for each  $v \in V$  there is an  $FG$ -submodule containing  $v$  of dimension  $\leq |G|$ .
5. Prove that if  $|G| > 1$  then every irreducible  $FG$ -module has dimension  $< |G|$ .
6. Write out the matrices  $\varphi(g)$  for every  $g \in G$  for each of the following representations that were described in the second set of examples:
  - (a) the representation of  $S_3$  described in Example 3 (let  $n = 3$  in that example)
  - (b) the representation of  $D_8$  described in Example 6 (i.e., let  $n = 4$  in that example and write out the values of all the sines and cosines, for all group elements)
  - (c) the representation of  $Q_8$  described in Example 7
  - (d) the representation of  $Q_8$  described in Example 8.
7. Let  $V$  be the 4-dimensional permutation module for  $S_4$  described in Example 3 of the second set of examples. Let  $\pi : D_8 \rightarrow S_4$  be the permutation representation of  $D_8$  obtained from the action of  $D_8$  by left multiplication on the set of left cosets of its subgroup  $\langle s \rangle$ . Make  $V$  into an  $FD_8$ -module via  $\pi$  as described in Example 4 and write out the  $4 \times 4$  matrices for  $r$  and  $s$  given by this representation with respect to the basis  $e_1, \dots, e_4$ .
8. Let  $V$  be the  $FS_n$ -module described in Examples 3 and 10 in the second set of examples.
  - (a) Prove that if  $v$  is any element of  $V$  such that  $\sigma \cdot v = v$  for all  $\sigma \in S_n$  then  $v$  is an  $F$ -multiple of  $e_1 + e_2 + \cdots + e_n$ .
  - (b) Prove that if  $n \geq 3$ , then  $V$  has a unique 1-dimensional submodule, namely the submodule  $N$  consisting of all  $F$ -multiples of  $e_1 + e_2 + \cdots + e_n$ .
9. Prove that the 4-dimensional representation of  $Q_8$  on  $\mathbb{H}$  described in Example 8 in the second set of examples is irreducible. [Show that any  $Q_8$ -stable subspace is a left ideal.]
10. Prove that  $GL_2(\mathbb{R})$  has no subgroup isomorphic to  $Q_8$ . [This may be done by direct computation using generators and relations for  $Q_8$ . Simplify these calculations by putting one generator in rational canonical form.]

11. Let  $\varphi : S_n \rightarrow GL_n(F)$  be the matrix representation given by the permutation module described in Example 3 in the second set of examples, where the matrices are computed with respect to the basis  $e_1, \dots, e_n$ . Prove that  $\det \varphi(\sigma) = \epsilon(\sigma)$  for all  $\sigma \in S_n$ , where  $\epsilon(\sigma)$  is the sign of the permutation  $\sigma$ . [Check this on transpositions.]
12. Assume the characteristic of  $F$  is not 2. Let  $H$  be the set of  $T \in M_n(F)$  such that  $T$  has exactly one nonzero entry in each row and each column and zeros elsewhere, and the nonzero entries are  $\pm 1$ . Prove that  $H$  is a subgroup of  $GL_n(F)$  and that  $H$  is isomorphic to  $E_{2^n} \rtimes S_n$  (semidirect product), where  $E_{2^n}$  is the elementary abelian group of order  $2^n$ .
- The next few exercises explore an important result known as Schur's Lemma and some of its consequences.
13. Let  $R$  be a ring and let  $M$  and  $N$  be simple (i.e., irreducible)  $R$ -modules.
- Prove that every nonzero  $R$ -module homomorphism from  $M$  to  $N$  is an isomorphism. [Consider its kernel and image.]
  - Prove Schur's Lemma: if  $M$  is a simple  $R$ -module then  $\text{Hom}_R(M, M)$  is a division ring (recall that  $\text{Hom}_R(M, M)$  is the ring of all  $R$ -module homomorphisms from  $M$  to  $M$ , where multiplication in this ring is composition).
14. Let  $\varphi : G \rightarrow GL(V)$  be a representation of  $G$ . The *centralizer* of  $\varphi$  is defined to be the set of all linear transformations,  $A$ , from  $V$  to itself such that  $A\varphi(g) = \varphi(g)A$  for all  $g \in G$  (i.e., the linear transformations of  $V$  which commute with all  $\varphi(g)$ 's).
- Prove that a linear transformation  $A$  from  $V$  to  $V$  is in the centralizer of  $\varphi$  if and only if it is an  $FG$ -module homomorphism from  $V$  to itself (so the centralizer of  $\varphi$  is the same as the *ring*  $\text{Hom}_{FG}(V, V)$ ).
  - Show that if  $z$  is in the center of  $G$  then  $\varphi(z)$  is in the centralizer of  $\varphi$ .
  - Assume  $\varphi$  is an irreducible representation (so  $V$  is a simple  $FG$ -module). Prove that if  $H$  is any finite *abelian* subgroup of  $GL(V)$  such that  $A\varphi(g) = \varphi(g)A$  for all  $A \in H$  then  $H$  is cyclic (in other words, any finite abelian subgroup of the multiplicative group of units in the ring  $\text{Hom}_{FG}(V, V)$  is cyclic). [By the preceding exercise,  $\text{Hom}_{FG}(V, V)$  is a division ring, so this reduces to proving that a finite abelian subgroup of the multiplicative group of nonzero elements in a division ring is cyclic. Show that the division subring generated by an abelian subgroup of any division ring is a field and use Proposition 18, Section 9.5.]
  - Show that if  $\varphi$  is a faithful irreducible representation then the center of  $G$  is cyclic.
  - Deduce from (d) that if  $G$  is abelian and  $\varphi$  is any irreducible representation then  $G/\ker \varphi$  is cyclic.
15. Exhibit all 1-dimensional complex representations of a finite cyclic group; make sure to decide which are inequivalent.
16. Exhibit all 1-dimensional complex representations of a finite abelian group. Deduce that the number of inequivalent degree 1 complex representations of a finite abelian group equals the order of the group. [First decompose the abelian group into a direct product of cyclic groups, then use the preceding exercise.]
17. Prove the following variant of Schur's Lemma for complex representations of abelian groups: if  $G$  is abelian, any irreducible complex representation,  $\varphi$ , of  $G$  is of degree 1 and  $G/\ker \varphi$  is cyclic. [This can be done without recourse to Exercise 14 by using the observation that for any  $g \in G$  the eigenspaces of  $\varphi(g)$  are  $G$ -stable. Your proof that  $\varphi$  has degree 1 should also work for infinite abelian groups.]
18. Prove the following general form of Schur's Lemma for complex representations: if  $\varphi : G \rightarrow GL_n(\mathbb{C})$  is an irreducible matrix representation and  $A$  is an  $n \times n$  matrix com-

muting with  $\varphi(g)$  for all  $g \in G$ , then  $A$  is a scalar matrix. Deduce that if  $\varphi$  is a faithful, irreducible, complex representation then the center of  $G$  is cyclic and  $\varphi(z)$  is a scalar matrix for all elements  $z$  in the center of  $G$ . [As in the preceding exercise, the eigenspaces of  $A$  are  $G$ -stable.]

19. Prove that if  $G$  is an abelian group then any finite dimensional complex representation of  $G$  is equivalent to a representation into diagonal matrices (i.e., any finite group of commuting matrices over  $\mathbb{C}$  can be simultaneously diagonalized). [This can be done without recourse to Maschke's Theorem by looking at eigenspaces.]
20. Prove that the number of degree 1 complex representations of any finite group  $G$  equals  $|G : G'|$ , where  $G'$  is the commutator subgroup of  $G$ . [Use Exercises 3 and 16.]
21. Let  $G$  be a noncyclic abelian group acting by conjugation on an elementary abelian  $p$ -group  $V$ , where  $p$  is a prime not dividing the order of  $G$ .
  - (a) Prove that if  $W$  is an irreducible  $\mathbb{F}_p G$ -submodule of  $V$  then there is some nonidentity element  $g \in G$  such that  $W \leq C_V(g)$  (here  $C_V(g)$  is the subgroup of elements of  $V$  that are fixed by  $g$  under conjugation).
  - (b) Prove that  $V$  is generated by the subgroups  $C_V(g)$  as  $g$  runs over all nonidentity elements of  $G$ .
22. Let  $p$  be a prime, let  $P$  be a  $p$ -group and let  $F$  be a field of characteristic  $p$ . Prove that the only irreducible representation of  $P$  over  $F$  is the trivial representation. [Do this for a group of order  $p$  first using the fact that  $F$  contains all  $p^{\text{th}}$  roots of 1 (namely 1 itself). If  $P$  is not of order  $p$ , let  $z$  be an element of order  $p$  in the center of  $P$ , prove that  $z$  is in the kernel of the irreducible representation and apply induction to  $P/(z)$ .]
23. Let  $p$  be a prime, let  $P$  be a nontrivial  $p$ -group and let  $F$  be a field of characteristic  $p$ . Prove that the regular representation is not completely reducible. [Use the preceding exercise.]
24. Let  $p$  be a prime, let  $P$  be a nontrivial  $p$ -group and let  $F$  be a field of characteristic  $p$ . Prove that the regular representation is indecomposable.

## 18.2 WEDDERBURN'S THEOREM AND SOME CONSEQUENCES

In this section we give a famous classification theorem due to Wedderburn which describes, in particular, the structure of the group algebra  $FG$  when the characteristic of  $F$  does not divide the order of  $G$ . From this classification theorem we shall derive various consequences, including the fact that for each finite group  $G$  there are only a finite number of nonisomorphic irreducible  $FG$ -modules. This result, together with Maschke's Theorem, in some sense completes the Hölder Program for representation theory of finite groups over such fields. The remainder of the book is concerned with developing techniques for determining and working with the irreducible representations as well as applying this knowledge to obtain group-theoretic information.

**Theorem 4. (Wedderburn's Theorem)** Let  $R$  be a nonzero ring with 1 (not necessarily commutative). Then the following are equivalent:

- (1) every  $R$ -module is projective
- (2) every  $R$ -module is injective
- (3) every  $R$ -module is completely reducible
- (4) the ring  $R$  considered as a left  $R$ -module is a direct sum:

$$R = L_1 \oplus L_2 \oplus \cdots \oplus L_n,$$

where each  $L_i$  is a simple module (i.e., a simple left ideal) with  $L_i = Re_i$ , for some  $e_i \in R$  with

- (i)  $e_i e_j = 0$  if  $i \neq j$
- (ii)  $e_i^2 = e_i$  for all  $i$
- (iii)  $\sum_{i=1}^n e_i = 1$

(5) as rings,  $R$  is isomorphic to a direct product of matrix rings over division rings, i.e.,  $R = R_1 \times R_2 \times \cdots \times R_r$ , where  $R_j$  is a two-sided ideal of  $R$  and  $R_j$  is isomorphic to the ring of all  $n_j \times n_j$  matrices with entries in a division ring  $\Delta_j$ ,  $j = 1, 2, \dots, r$ . The integer  $r$ , the integers  $n_j$ , and the division rings  $\Delta_j$  (up to isomorphism) are uniquely determined by  $R$ .

*Proof:* A proof of Wedderburn's Theorem is outlined in Exercises 1 to 10

**Definition.** A ring  $R$  satisfying any of the (equivalent) properties in Theorem 4 is called *semisimple with minimum condition*.

Rings  $R$  satisfying any of the equivalent conditions of Theorem 4 also satisfy the *minimum condition* or *descending chain condition (D.C.C.)* on left ideals:

if  $I_1 \supseteq I_2 \supseteq \cdots$  is a descending chain of left ideals of  $R$   
then there is an  $N \in \mathbb{Z}^+$  such that  $I_k = I_N$  for all  $k \geq N$

(which explains the use of this term in the definition above). The rings we deal with will all have this minimum condition. For example, group algebras always have this property since in any strictly descending chain of ideals the vector space dimensions of the ideals (which are  $F$ -subspaces of  $FG$ ) are strictly decreasing, hence the length of a strictly descending chain is at most the dimension of  $FG$  ( $= |G|$ ). We shall therefore use the term "semisimple" to mean "semisimple with minimum condition." The rings  $R_i$  in conclusion (5) of Wedderburn's Theorem are called the *Wedderburn components* of  $R$  and the direct product decomposition of  $R$  is called its *Wedderburn decomposition*. Note that Wedderburn's Theorem for commutative rings is a consequence of the classification of Artinian rings in Section 16.1. A commutative semisimple ring with minimum condition is an Artinian ring with Jacobson radical equal to zero and so is a direct product of fields (which are its Wedderburn components).

One should note that condition (5) is a two-sided condition which describes the overall structure of  $R$  completely (the ring operations in this direct product of rings are componentwise addition and multiplication). In particular it implies that a semisimple ring also has the minimum condition on right ideals: A useful way of thinking of the elements of the direct product  $R_1 \times \cdots \times R_r$  in conclusion (5) is as  $n \times n$  (block diagonal) matrices of the form

$$\begin{pmatrix} A_1 & & & \\ & A_2 & & \\ & & \ddots & \\ & & & A_r \end{pmatrix}$$

where  $A_i$  is an arbitrary  $n_i \times n_i$  matrix with entries from  $\Delta_i$  (here  $n = \sum_{i=1}^r n_i$ ).

Recall from Section 10.5 that an  $R$ -module  $Q$  is *injective* if whenever  $Q$  is a submodule of any  $R$ -module  $M$ , then  $M$  has a submodule  $N$  such that  $M = Q \oplus N$ . Maschke's Theorem therefore implies:

**Corollary 5.** If  $G$  is a finite group and  $F$  is a field whose characteristic does not divide  $|G|$ , then the group algebra  $FG$  is a semisimple ring.

Before obtaining more precise information about how the invariants  $n$ ,  $r$ ,  $\Delta_j$ , etc., relate to invariants in group rings  $FG$  for certain fields  $F$ , we first study the structure of matrix rings (i.e., the rings described in conclusions (4) and (5) of Wedderburn's Theorem). We introduce some terminology which is used extensively in ring theory. Recall that the *center* of the ring  $R$  is the subring of elements commuting with all elements in  $R$ ; it will be denoted by  $Z(R)$  (the center will contain 1 if the ring has a 1).

**Definition.**

- (1) A nonzero element  $e$  in a ring  $R$  is called an *idempotent* if  $e^2 = e$ .
- (2) Idempotents  $e_1$  and  $e_2$  are said to be *orthogonal* if  $e_1e_2 = e_2e_1 = 0$ .
- (3) An idempotent  $e$  is said to be *primitive* if it cannot be written as a sum of two (commuting) orthogonal idempotents.
- (4) The idempotent  $e$  is called a *primitive central idempotent* if  $e \in Z(R)$  and  $e$  cannot be written as a sum of two orthogonal idempotents in the ring  $Z(R)$ .

Proposition 6 describes the ideal structure of a matrix ring and Proposition 8 extends these results to direct products of matrix rings.

**Proposition 6.** Let  $\Delta$  be a division ring, let  $n \in \mathbb{Z}^+$ , let  $R$  be the ring of all  $n \times n$  matrices with entries from  $\Delta$  and let  $I$  be the identity matrix (= the 1 of  $R$ ).

- (1) The only two-sided ideals of  $R$  are 0 and  $R$ .
- (2) The center of  $R$  consists of the scalar matrices  $\alpha I$ , where  $\alpha$  is in the center of  $\Delta$ :  $Z(R) = \{\alpha I \mid \alpha \in Z(\Delta)\}$ , and this is a field isomorphic to  $Z(\Delta)$ . In particular, if  $\Delta$  is a field, the center of  $R$  is the subring of all scalar matrices. The only central idempotent in  $R$  is  $I$  (in particular,  $I$  is primitive).
- (3) Let  $e_i$  be the matrix with a 1 in position  $i, i$  and zeros elsewhere. Then  $e_1, \dots, e_n$  are orthogonal primitive idempotents and  $\sum_{i=1}^n e_i = I$ .
- (4)  $L_i = Re_i$  is the left ideal consisting of arbitrary entries in column  $i$  and zeros in all other columns.  $L_i$  is a simple left  $R$ -module. Every simple left  $R$ -module is isomorphic to  $L_1$  (in particular, all  $L_i$  are isomorphic  $R$ -modules) and as a left  $R$ -module we have  $R = L_1 \oplus \dots \oplus L_n$ .

Before proving this proposition it will be useful to have the following result.

**Lemma 7.** Let  $R$  be an arbitrary nonzero ring.

- (1) If  $M$  and  $N$  are simple  $R$ -modules and  $\varphi : M \rightarrow N$  is a nonzero  $R$ -module homomorphism, then  $\varphi$  is an isomorphism.
- (2) (*Schur's Lemma*) If  $M$  is a simple  $R$ -module, then  $\text{Hom}_R(M, M)$  is a division ring.

*Proof of Lemma 7:* To prove (1) note that since  $\varphi$  is nonzero,  $\ker \varphi$  is a proper submodule of  $M$ . By simplicity of  $M$  we have  $\ker \varphi = 0$ . Similarly, the image of  $\varphi$  is a nonzero submodule of the simple module  $N$ , hence  $\varphi(M) = N$ . This proves  $\varphi$  is bijective, so (1) holds.

By part (1), every nonzero element of the ring  $\text{Hom}_R(M, M)$  is an isomorphism, hence has an inverse. This gives (2).

*Proof of Proposition 6* Let  $A$  be an arbitrary matrix in  $R$  whose  $i, j$  entry is  $a_{ij}$ . Let  $E_{ij}$  be the matrix with a 1 in position  $i, j$  and zeros elsewhere. The following straightforward computations are left as exercises:

- (i)  $E_{ij}A$  is the matrix whose  $i^{\text{th}}$  row equals the  $j^{\text{th}}$  row of  $A$  and all other rows are zero.
- (ii)  $AE_{ij}$  is the matrix whose  $j^{\text{th}}$  column equals the  $i^{\text{th}}$  column of  $A$  and all other columns are zero.
- (iii)  $E_{pq}AE_{rs}$  is the matrix whose  $p, s$  entry is  $a_{qr}$  and all other entries are zero.

To prove (1) suppose  $J$  is any nonzero 2-sided ideal of  $R$  and let  $A$  be an element of  $J$  with a nonzero entry in position  $q, r$ . Given any  $p, s \in \{1, \dots, n\}$  we obtain from (iii) that

$$E_{ps} = \frac{1}{a_{qr}} E_{pq}AE_{rs} \in J.$$

Since the  $\Delta$ -linear combinations of  $\{E_{ps} \mid 1 \leq p \leq n, 1 \leq s \leq n\}$  give all of  $R$ , it follows that  $J = R$ . This proves (1).

To prove (2) assume  $A \in Z(R)$ . Thus for all  $i, j$  we have  $E_{ij}A = AE_{ij}$ . From (i) and (ii) above it follows immediately that all off-diagonal entries of  $A$  are zero and all diagonal entries of  $A$  are equal. Thus  $A = \alpha I$  for some  $\alpha \in \Delta$ . Furthermore,  $A$  must also commute with the set of all scalar matrices  $\beta I$ ,  $\beta \in \Delta$ , i.e.,  $\alpha$  must commute with all elements of  $\Delta$ . Finally, since  $Z(R)$  is a field, it is immediate that it contains a unique idempotent (namely  $I$ ). This establishes all parts of (2).

In part (3) it is clear that  $e_1, \dots, e_n$  are orthogonal idempotents whose sum is  $I$ . We defer proving that they are primitive until we have established (4).

Next we prove (4). From (ii) above it follows that  $Re_i = RE_{ii}$  is the set of matrices with arbitrary entries in the  $i^{\text{th}}$  column and zeros in all other columns. Furthermore, if  $A$  is any nonzero element of  $Re_i$ , then certainly  $RA \subseteq Re_i$ . The reverse inclusion holds because if  $a_{pi}$  is a nonzero entry of  $A$ , then by (i) above

$$e_i = E_{ii} = \frac{1}{a_{pi}} E_{ip}A \in RA.$$

This proves  $Re_i = RA$  for any nonzero element  $A \in Re_i$ , and so  $Re_i$  must be a simple  $R$ -module.

Let  $M$  be any simple  $R$ -module. Since  $Im = m$  for all  $m \in M$  and since  $I = \sum_{i=1}^n e_i$ , there exists some  $i$  and some  $m \in M$  such that  $e_i m \neq 0$ . For this  $i$  and  $m$  the map  $re_i \mapsto re_i m$  is a nonzero  $R$ -module homomorphism from the simple  $R$ -module  $Re_i$  to the simple module  $M$ . By Lemma 7(1) it is an isomorphism. By (ii), the map  $r \mapsto rE_{i1}$  gives  $Re_i \cong Re_1$ . Finally, every matrix is the direct sum of its columns so  $R = L_1 \oplus \dots \oplus L_n$ . This completes the proof of (4).

It remains to prove that the idempotents in part (3) are primitive. If  $e_i = a + b$ , for some orthogonal idempotents  $a$  and  $b$ , then we shall see that

$$L_i = Re_i = Ra \oplus Rb.$$

This will contradict the fact that  $L_i$  is a simple  $R$ -module. To establish the above direct sum note first that since  $ab = ba = 0$ , we have  $ae_i = a \in Re_i$  and  $be_i = b \in Re_i$ . For all  $r \in R$  we have  $re_i = ra + rb$ , hence  $Re_i = Ra + Rb$ . Moreover,  $Ra \cap Rb = 0$  because if  $ra = sb$  for some  $r, s \in R$ , then  $ra = raa = sba = 0$  (recall  $a = a^2$  and  $ba = 0$ ). This completes all parts of the proof.

**Proposition 8.** Let  $R = R_1 \times R_2 \times \cdots \times R_r$ , where  $R_i$  is the ring of  $n_i \times n_i$  matrices over the division ring  $\Delta_i$ , for  $i = 1, 2, \dots, r$ .

- (1) Identify  $R_i$  with the  $i^{\text{th}}$  component of the direct product. Let  $z_i$  be the  $r$ -tuple with the identity of  $R_i$  in position  $i$  and zero in all other positions. Then  $R_i = z_i R$  and for any  $a \in R_i$ ,  $z_i a = a$  and  $z_j a = 0$  for all  $j \neq i$ . The elements  $z_1, \dots, z_r$  are all of the primitive central idempotents of  $R$ . They are pairwise orthogonal and  $\sum_{i=1}^r z_i = 1$ .
- (2) Let  $N$  be any left  $R$ -module and let  $z_i N = \{z_i x \mid x \in N\}$ ,  $1 \leq i \leq r$ . Then  $z_i N$  is a left  $R$ -submodule of  $N$ , each  $z_i N$  is an  $R_i$ -module on which  $R_j$  acts trivially for all  $j \neq i$ , and

$$N = z_1 N \oplus z_2 N \oplus \cdots \oplus z_r N.$$

- (3) The simple  $R$ -modules are the simple  $R_i$ -modules on which  $R_j$  acts trivially for  $j \neq i$  in the following sense. Let  $M_i$  be the unique simple  $R_i$ -module (cf. Proposition 6). We may consider  $M_i$  as an  $R$ -module by letting  $R_j$  act trivially for all  $j \neq i$ . Then  $M_1, \dots, M_r$  are pairwise nonisomorphic simple  $R$ -modules and any simple  $R$ -module is isomorphic to one of  $M_1, \dots, M_r$ . Explicitly, the  $R$ -module  $M_i$  is isomorphic to the simple left ideal  $(0, \dots, 0, L^{(i)}, 0, \dots, 0)$  of all elements of  $R$  whose  $i^{\text{th}}$  component,  $L^{(i)}$ , consists of matrices with arbitrary entries in the first column and zeros elsewhere.
- (4) For any  $R$ -module  $N$  the  $R$ -submodule  $z_i N$  is a direct sum of simple  $R$ -modules, each of which is isomorphic to the module  $M_i$  in (3). In particular, if  $M$  is a simple  $R$ -module, then there is a unique  $i$  such that  $z_i M = M$  and for this index  $i$  we have  $M \cong M_i$ ; for all  $j \neq i$ ,  $z_j M = 0$ .
- (5) If each  $\Delta_i$  equals the field  $F$ , then  $R$  is a vector space over  $F$  of dimension  $\sum_{i=1}^r n_i^2$  and  $\dim_F Z(R) = r$ .

*Proof:* In part (1) since multiplication in the direct product of rings is componentwise it is clear that  $z_i$  times the element  $(a_1, \dots, a_r)$  of  $R$  is the  $r$ -tuple with  $a_i$  in position  $i$  and zeros elsewhere. Thus  $R_i = z_i R$ ,  $z_i$  is the identity in  $R_i$  and  $z_i a = 0$  if  $a \in R_j$  for any  $j \neq i$ . It is also clear that  $z_1, \dots, z_r$  are pairwise orthogonal central idempotents whose sum is the identity of  $R$ . The central idempotents of  $R$  are, by definition, the idempotents in  $Z(R) = F_1 \times F_2 \times \cdots \times F_r$ , where  $F_i$  is the center of  $R_i$ . By Proposition 6,  $F_i$  is the field  $Z(\Delta_i)$ . If  $w = (w_1, \dots, w_r)$  is any central idempotent then  $w_i \in F_i$  for all  $i$ , and since  $w^2 = w$  we have  $w_i^2 = w_i$  in the field  $F_i$ . Since 0 and 1 are the only solutions to  $x^2 = x$  in a field, the only central idempotents in  $R$  are  $r$ -tuples

whose entries are 0's and 1's. Thus  $z_1, \dots, z_r$  are primitive central idempotents and since every central idempotent is a sum of these, they are the complete set of primitive central idempotents of  $R$ . This proves (1).

To prove (2) let  $N$  be any left  $R$ -module. First note that for any  $z \in Z(R)$  the set  $\{zx \mid x \in N\}$  is an  $R$ -submodule of  $N$ . In particular,  $z_i N$  is an  $R$ -submodule. Let  $z_i x \in z_i N$  and let  $a \in R_j$  for some  $j \neq i$ . By (1) we have that  $a = az_j$  and so  $az_i x = (az_j)(z_i x) = az_i z_j x = 0$  because  $z_i z_j = 0$ . Thus the  $R$ -submodule  $z_i N$  is acted on trivially by  $R_j$  for all  $j \neq i$ . For each  $x \in N$  we have by (1) that  $x = 1x = z_1 x + \dots + z_r x$ , hence  $N = z_1 N + \dots + z_r N$ . Finally, this sum is direct because if, for instance,  $x \in z_1 N \cap (z_2 N + \dots + z_r N)$ , then  $x = z_1 x$  whereas  $z_1$  times any element of  $z_2 N + \dots + z_r N$  is zero. This proves (2).

In part (3) first note that an  $R_i$ -module  $M$  becomes an  $R$ -module when  $R_j$  is defined to act trivially on  $M$  for all  $j \neq i$ . For such a module  $M$  the  $R$ -submodules are the same as the  $R_i$ -submodules. Thus  $M_i$  is a simple  $R$ -module for each  $i$  since it is a simple  $R_i$ -module.

Next, let  $M$  be a simple  $R$ -module. By (2),  $M = z_1 M \oplus \dots \oplus z_r M$ . Since  $M$  has no nontrivial proper  $R$ -submodules, there must be a unique  $i$  such that  $M = z_i M$  and  $z_j M = 0$  for all  $j \neq i$ . Thus the simple  $R$ -module  $M$  is annihilated by  $R_j$  for all  $j \neq i$ . This implies that the  $R$ -submodules of  $M$  are the same as the  $R_i$ -submodules of  $M$ , so  $M$  is therefore a simple  $R_i$ -module. By Proposition 6,  $M$  is isomorphic as an  $R_i$ -module to  $M_i$ . Since  $R_j$  acts trivially on both  $M$  and  $M_i$  for all  $j \neq i$ , it follows that the  $R_i$ -module isomorphism may be viewed as an  $R$ -module isomorphism as well.

Suppose  $i \neq j$  and suppose  $\varphi : M_i \rightarrow M_j$  is an  $R$ -module isomorphism. If  $s_i \in M_i$  then  $s_i = z_i s_i$  so

$$\varphi(s_i) = \varphi(z_i s_i) = z_i \varphi(s_i) = 0,$$

since  $\varphi(s_i) \in M_j$  and  $z_i$  acts trivially on  $M_j$ . This contradicts the fact that  $\varphi$  is an isomorphism and proves that  $M_1, \dots, M_r$  are pairwise nonisomorphic simple  $R$ -modules.

Finally, the left ideal of  $R$  described in (3) is acted on trivially by  $R_j$  for all  $j \neq i$  and, by Proposition 6, it is up to isomorphism the unique simple  $R_i$ -module. This left ideal is therefore a simple  $R$ -module which is isomorphic to  $M_i$ . This proves (3).

For part (4) we have already proved that if  $M$  is any simple  $R$ -module then there is a unique  $i$  such that  $z_i M = M$  and  $z_j M = 0$  for all  $j \neq i$ . Furthermore, we have shown that for this index  $i$  the simple  $R$ -module  $M$  is isomorphic to  $M_i$ . Now let  $N$  be any  $R$ -module. Then  $z_i N$  is a module over  $R_i$  which is acted on trivially by  $R_j$  for all  $j \neq i$ . By Wedderburn's Theorem  $z_i N$  is a direct sum of simple  $R$ -modules. Since each of these simple summands is acted on trivially by  $R_j$  for all  $j \neq i$ , each is isomorphic to  $M_i$ . This proves (4).

In part (5) if each  $\Delta_i$  equals the field  $F$ , then as an  $F$ -vector space

$$R \cong M_{n_1}(F) \oplus M_{n_2}(F) \oplus \dots \oplus M_{n_r}(F).$$

Each matrix ring  $M_{n_i}(F)$  has dimension  $n_i^2$  over  $F$ , hence  $R$  has dimension  $\sum_{i=1}^r n_i^2$  over  $F$ . Furthermore, the center of each  $M_{n_i}(F)$  is 1-dimensional (since by Proposition 6(2) it is isomorphic to  $F$ ), hence  $Z(R)$  has dimension  $r$  over  $F$ . This completes the proof of the proposition.

We now apply Wedderburn's Theorem (and the above ring-theoretic calculations) to the group algebra  $FG$ . First of all, in order to apply Wedderburn's Theorem we need the characteristic of  $F$  not to divide  $|G|$ . In fact, since we shall be dealing with numerical data in the sections to come it will be convenient to have the characteristic of  $F$  equal to 0. Secondly, it will simplify matters if we force all the division rings which will appear in the Wedderburn decomposition of  $FG$  to equal the field  $F$  — we shall prove that imposing the condition that  $F$  be algebraically closed is sufficient to ensure this. To simplify notation we shall therefore take  $F = \mathbb{C}$  for most of the remainder of the text. The reader can easily check that any algebraically closed field of characteristic 0 (e.g., the field of all algebraic numbers) can be used throughout in place of  $\mathbb{C}$ .

By Corollary 5 the ring  $\mathbb{C}G$  is semisimple so by Wedderburn's Theorem

$$\mathbb{C}G \cong R_1 \times R_2 \times \cdots \times R_r$$

where  $R_i$  is the ring of  $n_i \times n_i$  matrices over some division ring  $\Delta_i$ . Thinking of the elements of this direct product as  $n \times n$  block matrices ( $n = \sum_{i=1}^r n_i$ ) where the  $i^{\text{th}}$  block has entries from  $\Delta_i$ , the field  $\mathbb{C}$  appears in this direct product as scalar matrices and is contained in the center of  $\mathbb{C}G$ . Note that each  $\Delta_i$  is a vector space over  $\mathbb{C}$  of dimension  $\leq n$ . The next result shows that this implies each  $\Delta_i = \mathbb{C}$ .

**Proposition 9.** If  $\Delta$  is a division ring that is a finite dimensional vector space over an algebraically closed field  $F$  and  $F \subseteq Z(\Delta)$ , then  $\Delta = F$ .

*Proof:* Since  $F \subseteq Z(\Delta)$ , for each  $\alpha \in \Delta$  the division ring generated by  $\alpha$  and  $F$  is a field. Also, since  $\Delta$  is finite dimensional over  $F$  the field  $F(\alpha)$  is a finite extension of  $F$ . Because  $F$  is algebraically closed it has no nontrivial finite extensions, hence  $F(\alpha) = F$  for all  $\alpha \in \Delta$ , i.e.,  $\Delta = F$ .

This proposition proves that each  $R_i$  in the Wedderburn decomposition of  $\mathbb{C}G$  is a matrix ring over  $\mathbb{C}$ :

$$R_i = M_{n_i}(\mathbb{C}).$$

Now Proposition 8(5) implies that

$$\sum_{i=1}^r n_i^2 = |G|.$$

The final application in this section is to prove that  $r$  (= the number of Wedderburn components in  $\mathbb{C}G$ ) equals the number of conjugacy classes of  $G$ . To see this, first note that Proposition 8(5) asserts that  $r = \dim_{\mathbb{C}} Z(\mathbb{C}G)$ . We compute this dimension in another way.

Let  $\mathcal{K}_1, \dots, \mathcal{K}_s$  be the distinct conjugacy classes of  $G$  (recall that these partition  $G$ ). For each conjugacy class  $\mathcal{K}_i$  of  $G$  let

$$X_i = \sum_{g \in \mathcal{K}_i} g \in \mathbb{C}G.$$

Note that  $X_i$  and  $X_j$  have no common terms for  $i \neq j$ , hence they are linearly independent elements of  $\mathbb{C}G$ . Furthermore, since conjugation by a group element permutes the

elements of each class,  $h^{-1}X_i h = X_i$ , i.e.,  $X_i$  commutes with all group elements. This proves that  $X_i \in Z(\mathbb{C}G)$ .

We show the  $X_i$ 's form a basis of  $Z(\mathbb{C}G)$ , which will prove  $s = \dim_{\mathbb{C}} Z(\mathbb{C}G) = r$ . Since the  $X_i$ 's are linearly independent it remains to show they span  $Z(\mathbb{C}G)$ . Let  $X = \sum_{g \in G} \alpha_g g$  be an arbitrary element of  $Z(\mathbb{C}G)$ . Since  $h^{-1}Xh = X$ ,

$$\sum_{g \in G} \alpha_g h^{-1}gh = \sum_{g \in G} \alpha_g g.$$

Since the elements of  $G$  form a basis of  $\mathbb{C}G$  the coefficients of  $g$  in the above two sums are equal:

$$\alpha_{hgh^{-1}} = \alpha_g.$$

Since  $h$  was arbitrary, every element in the same conjugacy class of a fixed group element  $g$  has the same coefficient in  $X$ , hence  $X$  can be written as a linear combination of the  $X_i$ 's.

We summarize these results in the following theorem.

**Theorem 10.** Let  $G$  be a finite group.

- (1)  $\mathbb{C}G \cong M_{n_1}(\mathbb{C}) \times M_{n_2}(\mathbb{C}) \times \cdots \times M_{n_r}(\mathbb{C})$ .
- (2)  $\mathbb{C}G$  has exactly  $r$  distinct isomorphism types of irreducible modules and these have complex dimensions  $n_1, n_2, \dots, n_r$  (and so  $G$  has exactly  $r$  inequivalent irreducible complex representations of the corresponding degrees).
- (3)  $\sum_{i=1}^r n_i^2 = |G|$ .
- (4)  $r$  equals the number of conjugacy classes in  $G$ .

**Corollary 11.**

- (1) Let  $A$  be a finite abelian group. Every irreducible complex representation of  $A$  is 1-dimensional (i.e., is a homomorphism from  $A$  into  $\mathbb{C}^\times$ ) and  $A$  has  $|A|$  inequivalent irreducible complex representations. Furthermore, every finite dimensional complex matrix representation of  $A$  is equivalent to a representation into a group of diagonal matrices.
- (2) The number of inequivalent (irreducible) degree 1 complex representations of any finite group  $G$  equals  $|G/G'|$ .

*Proof:* If  $A$  is abelian,  $\mathbb{C}A$  is a commutative ring. Since a  $k \times k$  matrix ring is not commutative whenever  $k > 1$  we must have each  $n_i = 1$ . Thus  $r = |A|$  (= the number of conjugacy classes of  $A$ ). Since every  $\mathbb{C}A$ -module is a direct sum of irreducible submodules, there is a basis such that the matrices are diagonal with respect to this basis. This establishes the first part of the corollary.

For a general group  $G$ , every degree 1 representation,  $\varphi$ , is a homomorphism of  $G$  into  $\mathbb{C}^\times$ . Thus  $\varphi$  factors through  $G/G'$ . Conversely, every degree 1 representation of  $G/G'$  gives, by composition with the natural projection  $G \rightarrow G/G'$ , a degree 1 representation of  $G$ . The degree 1 representations of  $G$  are therefore precisely the irreducible representations of the abelian group  $G/G'$ . Part (2) is now immediate from (1).

## Examples

- (1) The irreducible complex representations of a finite abelian group  $A$  (i.e., the homomorphisms from  $A$  into  $\mathbb{C}^\times$ ) can be explicitly described as follows: decompose  $A$  into a direct product of cyclic groups

$$A \cong C_1 \times \cdots \times C_n$$

where  $|C_i| = |\langle x_i \rangle| = d_i$ . Map each  $x_i$  to a (not necessarily primitive)  $d_i^{\text{th}}$  root of 1 and extend this to all powers of  $x_i$  to give a homomorphism. Since there are  $d_i$  choices for the image of each  $x_i$ , the number of distinct homomorphisms of  $A$  into  $\mathbb{C}^\times = GL_1(\mathbb{C})$  defined by this process equals  $|A|$ . By Corollary 11, these are all the irreducible representations of  $A$ . Note that it is necessary that the field contain the appropriate roots of 1 in order to realize these representations. An exercise below explores the irreducible representations of cyclic groups over  $\mathbb{Q}$ .

- (2) Let  $G = S_3$ . By Theorem 10 the number of irreducible complex representations of  $G$  is three (= the number of conjugacy classes of  $S_3$ ). Since the sum of the squares of the degrees is 6, the degrees must be 1, 1 and 2. The two degree 1 representations are immediately evident: the trivial representation and the representation of  $S_3$  into  $\{\pm 1\}$  given by mapping a permutation to its sign (i.e.,  $\sigma \mapsto +1$  if  $\sigma$  is an even permutation and  $\sigma \mapsto -1$  if  $\sigma$  is an odd permutation). The degree 2 representation can be found by decomposing the permutation representation on 3 basis vectors (described in Section 1) into irreducibles as follows: let  $S_3$  act on the basis vectors  $e_1, e_2, e_3$  of a vector space  $V$  by permuting their indices. The vector  $t = e_1 + e_2 + e_3$  is a nonzero fixed vector, so  $t$  spans a 1-dimensional  $G$ -invariant subspace (which is a copy of the trivial representation). By Maschke's Theorem there is a 2-dimensional  $G$ -invariant complement,  $I$ . Note that the permutation representation is not a sum of degree 1 representations: otherwise it could be represented by diagonal matrices and the permutations would commute in their action — this is impossible since the representation is faithful and  $G$  is non-abelian. Thus  $I$  cannot be decomposed further, so  $I$  affords the irreducible 2-dimensional representation. Indeed,  $I$  is the “augmentation” submodule described in Section 1:

$$I = \{w \in V \mid w = \alpha_1 e_1 + \alpha_2 e_2 + \alpha_3 e_3 \quad \text{with} \quad \alpha_1 + \alpha_2 + \alpha_3 = 0\}.$$

Clearly  $e_1 - e_2$  and  $e_2 - e_3$  are independent vectors in  $I$ , hence they form a basis for this 2-dimensional space. With respect to this basis of  $I$  we obtain a matrix representation of  $S_3$  and, for example, this matrix representation on two elements of  $S_3$  is

$$(1 \ 2) \mapsto \begin{pmatrix} -1 & 1 \\ 0 & 1 \end{pmatrix} \quad \text{and} \quad (1 \ 2 \ 3) \mapsto \begin{pmatrix} 0 & -1 \\ 1 & -1 \end{pmatrix}.$$

- (3) We decompose the regular representation over  $\mathbb{C}$  of an arbitrary finite group. Recall that this is the representation afforded by the left  $\mathbb{C}G$ -module  $\mathbb{C}G$  itself. By Theorem 10,  $\mathbb{C}G$  is first of all a direct product of two-sided ideals:

$$\mathbb{C}G \cong M_{n_1}(\mathbb{C}) \times M_{n_2}(\mathbb{C}) \times \cdots \times M_{n_r}(\mathbb{C}).$$

Now by Proposition 6(4) each  $M_{n_i}(\mathbb{C})$  decomposes further as a direct sum of  $n_i$  isomorphic simple left ideals. These left ideals give a complete set of isomorphism classes of irreducible  $\mathbb{C}G$ -modules. Thus the regular representation (over  $\mathbb{C}$ ) of  $G$  decomposes as the direct sum of all irreducible representations of  $G$ , each appearing with multiplicity equal to the degree of that irreducible representation.

We record one additional property of  $\mathbb{C}G$  which we shall prove in Section 19.2.

**Theorem 12.** The degree of each complex irreducible representation of a finite group  $G$  divides the order of  $G$ , i.e., in the notation of Theorem 10, each  $n_i$  divides  $|G|$  for  $i = 1, 2, \dots, r$ .

In the next section we shall describe the primitive central idempotents of  $\mathbb{C}G$  in terms of the group elements.

## EXERCISES

Let  $G$  be a finite group and let  $R$  be a ring with 1.

1. Prove that conditions (1) and (2) of Wedderburn's Theorem are equivalent.
2. Prove that (3) implies (2) in Wedderburn's Theorem. [Let  $Q$  be a submodule of an  $R$ -module  $N$ . Use Zorn's Lemma to show there is a submodule  $M$  maximal with respect to  $Q \cap M = 0$ . If  $Q + M = N$ , then (2) holds; otherwise let  $M_1$  be the complete preimage in  $N$  of some simple module in  $N/M$  not contained in  $(Q + M)/M$ , and argue that  $M_1$  contradicts the maximality of  $M$ .]
3. Prove that (4) implies (3) in Wedderburn's Theorem. [Let  $N$  be a nonzero  $R$ -module. First show  $N$  contains simple submodules by considering a cyclic submodule. Then use Zorn's Lemma applied to the set of direct sums of simple submodules (appropriately ordered) to show that  $N$  contains a maximal completely reducible submodule  $M$ . If  $M \neq N$  let  $M_1$  be the complete preimage in  $N$  of a simple module in  $N/M$  and contradict the maximality of  $M$ .]
4. Prove that (5) implies (4) in Wedderburn's Theorem. [Use the methods in the proofs of Propositions 6 and 8 to decompose each  $R_i$  as a left  $R$ -module.]

The next six exercises establish some general results about rings and modules that imply the remaining implication of Wedderburn's Theorem: (2) implies (5). In these exercises assume  $R$  satisfies (2): every  $R$ -module is injective.

5. Show that  $R$  has the descending chain condition (D.C.C.) on left ideals. Deduce that  $R$  is a finite direct sum of left ideals. [If not, then show that as a left  $R$ -module  $R$  is a direct sum of an infinite number of nonzero submodules. Derive a contradiction by writing the element 1 in this direct sum.]
6. Show that  $R = R_1 \times R_2 \times \dots \times R_r$ , where  $R_j$  is a 2-sided ideal and a simple ring (i.e., has no proper, nonzero 2-sided ideals). Show each  $R_j$  has an identity and satisfies D.C.C. on left ideals. [Use the preceding exercise to show  $R$  has a minimal 2-sided ideal  $R_1$ . As a left  $R$ -module  $R = R_1 \oplus R'$  for some left ideal  $R'$ . Show  $R'$  is a right ideal and proceed inductively using D.C.C.]
7. Let  $S$  be a simple ring with 1 satisfying D.C.C. on left ideals and let  $L$  be a minimal left ideal in  $S$ . Show that  $S \cong L^n$  as left  $S$ -modules, where  $L^n = L \oplus \dots \oplus L$  with  $n$  factors. [Argue by simplicity that  $LS = S$  so  $1 = l_1 s_1 + \dots + l_n s_n$  for some  $l_i \in L$  and  $s_i \in S$  with  $n$  minimal. Show that the map  $(x_1, \dots, x_n) \mapsto x_1 s_1 + \dots + x_n s_n$  is a surjective homomorphism of left  $S$ -modules; use the minimality of  $L$  and  $n$  to show it is an injection.]
8. Let  $A$  be any ring with 1, let  $L$  be any left  $A$ -module and let  $L^n$  be the direct sum of  $n$  copies of  $L$  with itself.
  - (a) Prove the ring isomorphism  $\text{Hom}_A(L^n, L^n) \cong M_n(D)$ , where  $D = \text{Hom}_A(L, L)$  (multiplication in the ring  $\text{Hom}_A(X, X)$  is function composition, cf. Proposition 2(4) in Section 10.2).

- (b) Deduce that if  $L$  is a simple  $A$ -module, then  $\text{Hom}_A(L^n, L^n)$  is isomorphic to a matrix ring over a division ring. [Use Schur's Lemma and (a).]
- (c) Prove the ring isomorphism  $\text{Hom}_A(A, A) \cong A^{\text{opp}}$ , where  $A^{\text{opp}}$  is the opposite ring to  $A$  (the elements and addition are the same as in  $A$  but the value of the product  $x \cdot y$  in  $A^{\text{opp}}$  is  $yx$ , computed in  $A$ ), cf. the end of Section 17.4. [Any homomorphism is determined by its value on 1.]
9. Prove that if  $S$  is a simple ring with 1 satisfying D.C.C. on left ideals then  $S \cong M_n(\Delta)$  for some division ring  $\Delta$ . (This result together with Exercise 6 completes the existence part of the proof that (2) implies (5) in Wedderburn's Theorem). [Use Exercises 7 and 8 to show  $S^{\text{opp}} \cong \text{Hom}_S(L^n, L^n) \cong M_n(D)$  for some division ring  $D$ . Then show  $S \cong M_n(\Delta)$ , where  $\Delta$  is the division ring  $D^{\text{opp}}$ .]
10. Prove that  $\Delta$  and  $n$  in the isomorphism  $S \cong M_n(\Delta)$  of the previous exercise are uniquely determined by  $S$  (proving the uniqueness statement in Wedderburn's Theorem), as follows. Suppose  $S = M_n(\Delta) \cong M_{n'}(\Delta')$  as rings, where  $\Delta$  and  $\Delta'$  are division rings.
- Prove that  $\Delta \cong \text{Hom}_S(L, L)$  where  $L$  is a minimal left ideal in  $S$ . Deduce that  $\Delta \cong \Delta'$ . [Use Proposition 6(4).]
  - Prove that a finitely generated (left) module over a division ring  $\Delta$  has a “basis” (a linearly independent generating set), and that any two bases have the same cardinality. Deduce that  $n = n'$ . [Mimic the proof of Corollary 4(2) of Section 11.1.]
11. Prove that if  $R$  is a ring with 1 such that every  $R$ -module is free then  $R$  is a division ring.
12. Let  $F$  be a field, let  $f(x) \in F[x]$  and let  $R = F[x]/(f(x))$ . Find necessary and sufficient conditions on the factorization of  $f(x)$  in  $F[x]$  so that  $R$  is a semisimple ring. When  $R$  is semisimple, describe its Wedderburn decomposition. [See Proposition 16 in Section 9.5.]
13. Let  $G$  be the cyclic group of order  $n$  and let  $R = \mathbb{Q}G$ . Describe the Wedderburn decomposition of  $R$  and find the number and the degrees of the irreducible representations of  $G$  over  $\mathbb{Q}$ . In particular, show that if  $n = p$  is a prime then  $G$  has exactly one nontrivial irreducible representation over  $\mathbb{Q}$  and this representation has degree  $p - 1$ . [Recall from the first example in Section 1 that  $\mathbb{Q}G = \mathbb{Q}[x]/(x^n - 1)$ . Use Proposition 16 in Section 9.5 and results from Section 13.6.]
14. Let  $p$  be a prime and let  $F = \mathbb{F}_p$  be the field of order  $p$ . Let  $G$  be the cyclic group of order 3 and let  $R = FG$ . For each of  $p = 2$  and  $p = 7$  describe the Wedderburn decomposition of  $R$  and find the number and the degrees of the irreducible representations of  $G$  over  $F$ .
15. Prove that if  $P$  is a  $p$ -group for some prime  $p$ , then  $P$  has a faithful irreducible complex representation if and only if  $Z(P)$  is cyclic. [Use Exercise 18 in Section 1, Theorem 6.1(2) and Example 3.]
16. Prove that if  $V$  is an irreducible  $FG$ -module and  $F$  is an algebraically closed field then  $\text{Hom}_{FG}(V, V)$  is isomorphic to  $F$  (as a ring).
17. Let  $F$  be a field, let  $R = M_n(F)$  and let  $M$  be the unique irreducible  $R$ -module. Prove that  $\text{Hom}_R(M, M)$  is isomorphic to  $F$  (as a ring).
18. Find all 2-sided ideals of  $M_n(\mathbb{Z})$ .

### 18.3 CHARACTER THEORY AND THE ORTHOGONALITY RELATIONS

In general, for groups of large order the representations are difficult to compute and unwieldy if not impossible to write down. For example, a matrix representation of degree 100 involves matrices with 10,000 entries, and a number of  $100 \times 100$  matrices

may be required to describe the representation, even on a set of generators for the group. There are, however, some striking examples where large degree representations have been computed and used effectively. One instance of this is a construction of the simple group  $J_1$  by Z. Janko in 1965 (the existence problem for simple groups was discussed at the end of Section 6.2). Janko was investigating certain properties of simple groups and he found that if any simple group possessed these properties, then it would necessarily have order 175,560 and would be generated by two elements. Furthermore, he proved that a hypothetical simple group with these properties must have a 7-dimensional representation over the field  $\mathbb{F}_{11}$  with two generators mapping to the two matrices

$$\left( \begin{array}{ccccccc} 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 \end{array} \right) \text{ and } \left( \begin{array}{ccccccc} -3 & 2 & -1 & -1 & -3 & -1 & -3 \\ -2 & 1 & 1 & 3 & 1 & 3 & 3 \\ -1 & -1 & -3 & -1 & -3 & -3 & 2 \\ -1 & -3 & -1 & -3 & -3 & 2 & -1 \\ -3 & -1 & -3 & -3 & 2 & -1 & -1 \\ 1 & 3 & 3 & -2 & 1 & 1 & 3 \\ 3 & 3 & -2 & 1 & 1 & 3 & 1 \end{array} \right)$$

(note that for any simple group  $S$ , every representation of  $S$  into  $GL_n(F)$  which does not map all group elements to the identity matrix is a faithful representation, so  $S$  is isomorphic to its image in  $GL_n(F)$ ). In particular, Janko's calculations showed that the simple group satisfying his properties was unique, if it existed. M. Ward was able to show that these two matrices do generate a subgroup of  $GL_7(\mathbb{F}_{11})$  of order 175,560 and it follows that there does exist a simple group satisfying Janko's properties.

In a similar vein, S. Norton, R. Parker and J. Thackray constructed the simple group  $J_4$  of order 86,775,571,046,077,562,880 using a 112-dimensional representation over  $\mathbb{F}_2$ . This group was shown to be generated by two elements, and explicit matrices in  $GL_{112}(\mathbb{F}_2)$  for these two generators were computed in the course of their analysis.

In 1981, R. Griess constructed the largest of the sporadic groups, the so called *Monster*, of order

$$2^{46} \cdot 3^{20} \cdot 5^9 \cdot 7^6 \cdot 11^2 \cdot 13^3 \cdot 17 \cdot 19 \cdot 23 \cdot 29 \cdot 31 \cdot 41 \cdot 47 \cdot 59 \cdot 71.$$

His proof involves calculations of automorphisms of an algebra over  $\mathbb{C}$  of dimension 196,884 and leads to a construction of the Monster by means of a representation of this degree.

By analogy, in general it is difficult to write out the explicit permutations associated to a permutation representation  $\varphi : G \rightarrow S_n$  for large degrees  $n$ . There are, however, numerical invariants such as the signs and the cycle types of the permutations  $\pi(g)$  and these numerical invariants might be easier to compute than the permutations themselves (i.e., it may be possible to determine the cycle types of elements without actually having to write out the permutations themselves, as in the computation of Galois groups over  $\mathbb{Q}$  in Section 14.8). These invariants alone may provide enough information in a given situation to carry out some analysis, such as prove that a given group is not simple (as illustrated in Section 6.2). Furthermore, the invariants just mentioned do not depend on the labelling of the set  $\{1, 2, \dots, n\}$  (i.e., they are independent of a “change of basis” in  $S_n$ ) and they are the same for elements that are conjugate in  $G$ .

In this section we show how to attach numerical invariants to linear representations. These invariants depend only on the equivalence class (isomorphism type) of the representation. In other words, for each representation  $\varphi : G \rightarrow GL_n(F)$  we shall attach an element of  $F$  to each matrix  $\varphi(g)$  and we shall see that this number can, in many instances, be computed without knowing the matrix  $\varphi(g)$ . Moreover, we shall see that these invariants are independent of the similarity class of  $\varphi$  (i.e., are the same for a fixed  $g \in G$  if the representation  $\varphi$  is replaced by an equivalent representation) and that they, in some sense, characterize the similarity classes of representations of  $G$ .

Throughout this section  $G$  is a finite group and, for the moment,  $F$  is an arbitrary field. All representations considered are assumed to be finite dimensional.

### Definition.

- (1) A *class function* is any function from  $G$  into  $F$  which is constant on the conjugacy classes of  $G$ , i.e.,  $f : G \rightarrow F$  such that  $f(g^{-1}xg) = f(x)$  for all  $g, x \in G$ .
- (2) If  $\varphi$  is a representation of  $G$  afforded by the  $FG$ -module  $V$ , the *character* of  $\varphi$  is the function

$$\chi : G \rightarrow F \quad \text{defined by} \quad \chi(g) = \operatorname{tr} \varphi(g),$$

where  $\operatorname{tr} \varphi(g)$  is the trace of the matrix of  $\varphi(g)$  with respect to some basis of  $V$  (i.e., the sum of the diagonal entries of that matrix). The character is called *irreducible* or *reducible* according to whether the representation is irreducible or reducible, respectively. The *degree* of a character is the degree of any representation affording it.

In the notation of the second part of this definition we shall also refer to  $\chi$  as the character afforded by the  $FG$ -module  $V$ . In general, a character is *not* a homomorphism from a group into either the additive or multiplicative group of the field.

### Examples

- (1) The character of the trivial representation is the function  $\chi(g) = 1$  for all  $g \in G$ . This character is called the *principal* character of  $G$ .
- (2) For degree 1 representations, the character and the representation are usually identified (by identifying a  $1 \times 1$  matrix with its entry). Thus for abelian groups, irreducible complex representations and their characters are the same (cf. Corollary 11).
- (3) Let  $\Pi : G \rightarrow S_n$  be a permutation representation and let  $\varphi$  be the resulting linear representation on the basis  $e_1, \dots, e_n$  of the vector space  $V$ :

$$\varphi(g)(e_i) = e_{\Pi(g)(i)}$$

(cf. Example 4 of Section 1). With respect to this basis the matrix of  $\varphi(g)$  has a 1 in the diagonal entry  $i, i$  if  $\Pi(g)$  fixes  $i$ ; otherwise, the matrix of  $\varphi(g)$  has a zero in position  $i, i$ . Thus if  $\pi$  is the character of  $\varphi$  then

$$\pi(g) = \text{the number of fixed points of } g \text{ on } \{1, 2, \dots, n\}.$$

In particular, if  $\Pi$  is the permutation representation obtained from left multiplication on the set of left cosets of some subgroup  $H$  of  $G$  then the resulting character is called the *permutation character* of  $G$  on  $H$ .

- (4) The special case of Example 3 when  $\Pi$  is the regular permutation representation of  $G$  is worth recording: if  $\varphi$  is the regular representation of  $G$  (afforded by the module  $FG$ ) and  $\rho$  is its character:

$$\rho(g) = \begin{cases} 0 & \text{if } g \neq 1 \\ |G| & \text{if } g = 1. \end{cases}$$

The character of the regular representation of  $G$  is called the *regular character* of  $G$ . Note that this provides specific examples where a character takes on the value 0 and is not a group homomorphism from  $G$  into either  $F$  or  $F^\times$ .

- (5) Let  $\varphi : D_{2n} \rightarrow GL_2(\mathbb{R})$  be the explicit matrix representation described in Example 6 in the second set of examples of Section 1. If  $\chi$  is the character of  $\varphi$  then, by taking traces of the given  $2 \times 2$  matrices one sees that  $\chi(r) = 2 \cos(2\pi/n)$  and  $\chi(s) = 0$ . Since  $\varphi$  takes the identity of  $D_{2n}$  to the  $2 \times 2$  identity matrix,  $\chi(1) = 2$ .
- (6) Let  $\varphi : Q_8 \rightarrow GL_2(\mathbb{C})$  be the explicit matrix representation described in Example 7 in the second set of examples of Section 1. If  $\chi$  is the character of  $\varphi$  then, by taking traces of the given  $2 \times 2$  matrices,  $\chi(i) = 0$  and  $\chi(j) = 0$ . Since the element  $-1 \in Q_8$  maps to minus the  $2 \times 2$  identity matrix,  $\chi(-1) = -2$ . Since  $\varphi$  takes the identity of  $Q_8$  to the  $2 \times 2$  identity matrix,  $\chi(1) = 2$ .
- (7) Let  $\varphi : Q_8 \rightarrow GL_4(\mathbb{R})$  be the matrix representation described in Example 8 in the second set of examples of Section 1. If  $\chi$  is the character of  $\varphi$  then, by inspection of the matrices exhibited,  $\chi(i) = \chi(j) = 0$ . Since  $\varphi$  takes the identity of  $Q_8$  to the  $4 \times 4$  identity matrix,  $\chi(1) = 4$ .

For  $n \times n$  matrices  $A$  and  $B$ , direct computation shows that  $\text{tr } AB = \text{tr } BA$ . If  $A$  is invertible, this implies that

$$\text{tr } A^{-1}BA = \text{tr } B.$$

Thus the character of a representation is independent of the choice of basis of the vector space affording it, i.e.,

$$\text{equivalent representations have the same character.} \quad (18.1)$$

Let  $\varphi$  be a representation of  $G$  of degree  $n$  with character  $\chi$ . Since  $\varphi(g^{-1}xg)$  is  $\varphi(g)^{-1}\varphi(x)\varphi(g)$  for all  $g, x \in G$ , taking traces shows that

$$\text{the character of a representation is a class function.} \quad (18.2)$$

Since the trace of the  $n \times n$  identity matrix is  $n$  and  $\varphi$  takes the identity of  $G$  to the identity linear transformation (or matrix),

$$\chi(1) \text{ is the degree of } \varphi. \quad (18.3)$$

If  $V$  is an  $FG$ -module whose corresponding representation has character  $\chi$ , then each element of the group ring  $FG$  acts as a linear transformation from  $V$  to  $V$ . Thus each  $\sum_{g \in G} \alpha_g g \in FG$  has a trace when it is considered as a linear transformation from  $V$  to  $V$ . The trace of  $g \in G$  acting on  $V$  is, by definition,  $\chi(g)$ . Since the trace of any linear combination of matrices is the linear combination of the traces, the trace of  $\sum_{g \in G} \alpha_g g$  acting on  $V$  is  $\sum_{g \in G} \alpha_g \chi(g)$ . Note that this trace function on  $FG$  is the unique extension of the character  $\chi$  of  $G$  to an  $F$ -linear transformation from  $FG$  to  $F$ . In this way we shall consider characters of  $G$  as also being defined on the group ring  $FG$ .

Notice in Example 3 above that if the field  $F$  has characteristic  $p > 0$ , the values of the character mod  $p$  might be zero even though the number of fixed points is nonzero. In order to circumvent such anomalies and to use the consequences of Wedderburn's Theorem obtained when  $F$  is algebraically closed we again specialize the field to be the complex numbers (or any algebraically closed field of characteristic 0). By the results of the previous section

$$\mathbb{C}G \cong M_{n_1}(\mathbb{C}) \times M_{n_2}(\mathbb{C}) \times \cdots \times M_{n_r}(\mathbb{C}). \quad (18.4)$$

For the remainder of this section fix the following notation:

$$\begin{aligned} M_1, M_2, \dots, M_r &\text{ are the inequivalent irreducible } \mathbb{C}G\text{-modules,} \\ \chi_i &\text{ is the character afforded by } M_i, \quad 1 \leq i \leq r. \end{aligned} \quad (18.5)$$

Thus  $r$  is the number of conjugacy classes of  $G$  and we may relabel  $M_1, \dots, M_r$  if necessary so that the degree of  $\chi_i$  is  $n_i$  for all  $i$  (which is also the dimension of  $M_i$  over  $\mathbb{C}$ ).

Now every (finite dimensional)  $\mathbb{C}G$ -module  $M$  is isomorphic (equivalent) to a direct sum of irreducible modules:

$$M \cong a_1 M_1 \oplus a_2 M_2 \oplus \cdots \oplus a_r M_r, \quad (18.6)$$

where  $a_i$  is a nonnegative integer indicating the multiplicity of the irreducible module  $M_i$  in this direct sum decomposition, i.e.,

$$a_i M_i = \overbrace{M_i \oplus \cdots \oplus M_i}^{a_i \text{ times}}.$$

Note that if the representation  $\varphi$  is afforded by the module  $M$  and  $M = M_1 \oplus M_2$ , then we may choose a basis of  $M$  consisting of a basis of  $M_1$  together with a basis of  $M_2$ . The matrix representation with respect to this basis is of the form

$$\varphi(g) = \begin{pmatrix} \varphi_1(g) & 0 \\ 0 & \varphi_2(g) \end{pmatrix}$$

where  $\varphi_i$  is the representation afforded by  $M_i$ ,  $i = 1, 2$ . One sees immediately that if  $\psi$  is the character of  $\varphi$  and  $\psi_i$  is the character of  $\varphi_i$ , then  $\psi(g) = \psi_1(g) + \psi_2(g)$ , i.e.,  $\psi = \psi_1 + \psi_2$ . By induction we obtain:

$$\begin{aligned} \text{the character of a representation is the sum of the characters} \\ \text{of the constituents appearing in a direct sum decomposition.} \end{aligned} \quad (18.7)$$

If  $\psi$  is the character afforded by the module  $M$  in (6) above, this gives

$$\psi = a_1 \chi_1 + a_2 \chi_2 + \cdots + a_r \chi_r. \quad (18.8)$$

Thus every (complex) character is a nonnegative integral sum of irreducible (complex) characters. Conversely, by taking direct sums of modules one sees that every such sum of characters is the character of some complex representation of  $G$ .

We next prove that the correspondence between characters and equivalence classes of complex representations is *bijective*. Let  $z_1, z_2, \dots, z_r$  be the primitive central idempotents of  $\mathbb{C}G$  described in the preceding section. Since these are orthogonal (or equivalently, since they are the  $r$ -tuples in the decomposition of  $\mathbb{C}G$  into a direct product of  $r$

substrings which have a 1 in one position and zeros elsewhere),  $z_1, \dots, z_r$  are  $\mathbb{C}$ -linearly independent elements of  $\mathbb{C}G$ . As above, each irreducible character  $\chi_i$  is a function on  $\mathbb{C}G$ . By Proposition 8(3) we have

- (a) if  $j \neq i$  then  $z_j M_i = 0$ , i.e.,  $z_j$  acts as the zero matrix on  $M_i$ , hence  $\chi_j(z_i) = 0$ , and
- (b)  $z_i$  acts as the identity on  $M_i$ , hence  $\chi_i(z_i) = n_i$ .

Thus  $\chi_1, \dots, \chi_r$  are multiples of the dual basis to the independent set  $z_1, \dots, z_r$ , hence are linearly independent functions. Now if the  $\mathbb{C}G$ -module  $M$  described in (6) above can be decomposed in a different fashion into irreducibles, say,

$$M \cong b_1 M_1 \oplus b_2 M_2 \oplus \cdots \oplus b_r M_r,$$

then we would obtain a relation

$$a_1 \chi_1 + a_2 \chi_2 + \cdots + a_r \chi_r = b_1 \chi_1 + b_2 \chi_2 + \cdots + b_r \chi_r.$$

By linear independence of the irreducible characters,  $b_i = a_i$  for all  $i \in \{1, \dots, r\}$ . Thus, in any decomposition of  $M$  into a direct sum of irreducibles, the multiplicity of the irreducible  $M_i$  is the same,  $1 \leq i \leq r$ . In particular,

*two representations are equivalent if and only if they have the same character.* (18.9)

This uniqueness can be seen in an alternate way. First, use Proposition 8(2) to decompose an arbitrary finite dimensional  $\mathbb{C}G$ -module  $M$  uniquely as

$$M = z_1 M \oplus z_2 M \oplus \cdots \oplus z_r M.$$

By part (4) of the same proposition,  $z_i M$  is a direct sum of simple modules, each of which is isomorphic to  $M_i$ . The multiplicity of  $M_i$  in a direct sum decomposition of  $z_i M$  is, by counting dimensions, equal to  $\frac{\dim z_i M}{\dim M_i}$ . This proves that the multiplicity of  $M_i$  in any direct sum decomposition of  $M$  into simple submodules is uniquely determined.

Note that, as with decompositions of  $F[x]$ -modules into cyclic submodules, a  $\mathbb{C}G$ -module may have many direct sum decompositions into irreducibles — only the multiplicities are unique (see also the exercises). More precisely, comparing with the Jordan canonical form of a single linear transformation, the direct summand  $a_i M_i = M_i \oplus \cdots \oplus M_i$  ( $a_i$  times) which equals the submodule  $z_i M$  is the analogue of the generalized eigenspace corresponding to a single eigenvalue. This submodule of  $M$  is unique (as is a generalized eigenspace) and is called the  $\chi_i^{\text{th}}$  *isotypic component* of  $M$ . Within the  $\chi_i^{\text{th}}$  isotypic component, the summands  $M_i$  are analogous to the 1-dimensional eigenspaces and, just as with the eigenspace of an endomorphism there is no unique basis for the eigenspace. If  $G = \langle g \rangle$  is a finite cyclic group, the isotypic components of  $G$  are the same as the generalized eigenspaces of  $g$ .

Observe that the vector space of all (complex valued) class functions on  $G$  has a basis consisting of the functions which are 1 on a given class and zero on all other classes. There are  $r$  of these, where  $r$  is the number of conjugacy classes of  $G$ , so the dimension of the complex vector space of class functions is  $r$ . Since the number of

(complex) irreducible characters of  $G$  equals the number of conjugacy classes and these are linearly independent class functions, we see that

$$\text{the irreducible characters are a basis for the space of all complex class functions.} \quad (18.10)$$

The next step in the theory of characters is to put an Hermitian inner product structure on the space of class functions and prove that the irreducible characters form an orthonormal basis with respect to this inner product. For class functions  $\theta$  and  $\psi$  define

$$(\theta, \psi) = \frac{1}{|G|} \sum_{g \in G} \theta(g) \overline{\psi(g)}$$

(where the bar denotes complex conjugation). One easily checks that  $( , )$  is Hermitian: for  $\alpha, \beta \in \mathbb{C}$

- (a)  $(\alpha\theta_1 + \beta\theta_2, \psi) = \alpha(\theta_1, \psi) + \beta(\theta_2, \psi)$ ,
- (b)  $(\theta, \alpha\psi_1 + \beta\psi_2) = \overline{\alpha}(\theta, \psi_1) + \overline{\beta}(\theta, \psi_2)$ , and
- (c)  $(\theta, \psi) = (\overline{\psi}, \theta)$ .

Our principal aim is to show that the irreducible characters form an orthonormal basis for the space of complex class functions with respect to this Hermitian form (we already know that they are a basis). This fact will follow from the orthogonality of the primitive central idempotents, once we have explicitly determined these in the next proposition.

**Proposition 13.** Let  $z_1, \dots, z_r$  be the orthogonal primitive central idempotents in  $\mathbb{C}G$  labelled in such a way that  $z_i$  acts as the identity on the irreducible  $\mathbb{C}G$ -module  $M_i$ , and let  $\chi_i$  be the character afforded by  $M_i$ . Then

$$z_i = \frac{\chi_i(1)}{|G|} \sum_{g \in G} \chi_i(g^{-1}) g.$$

*Proof:* Let  $z = z_i$  and write

$$z = \sum_{g \in G} \alpha_g g.$$

Recall from Example 4 in this section that if  $\rho$  is the regular character of  $G$  then

$$\rho(g) = \begin{cases} 0 & \text{if } g \neq 1 \\ |G| & \text{if } g = 1 \end{cases} \quad (18.11)$$

and recall from the last example in Section 2 that

$$\rho = \sum_{j=1}^r \chi_j(1) \chi_j. \quad (18.12)$$

To find the coefficient  $\alpha_g$ , apply  $\rho$  to  $zg^{-1}$  and use linearity of  $\rho$  together with equation (11) to obtain

$$\rho(zg^{-1}) = \alpha_g |G|.$$

Computing  $\rho(zg^{-1})$  using (12) then gives

$$\sum_{j=1}^r \chi_j(1)\chi_j(zg^{-1}) = \alpha_g|G|. \quad (18.13)$$

Let  $\varphi_j$  be the irreducible representation afforded by  $M_j$ ,  $1 \leq j \leq r$ . Since we may consider  $\varphi_j$  as an algebra homomorphism from  $\mathbb{C}G$  into  $\text{End}(M_j)$ , we obtain  $\varphi_j(zg^{-1}) = \varphi_j(z)\varphi_j(g^{-1})$ . Also, we have already observed that  $\varphi_j(z)$  is 0 if  $j \neq i$  and  $\varphi_i(z)$  is the identity endomorphism on  $M_i$ . Thus

$$\varphi_j(zg^{-1}) = \begin{cases} 0 & \text{if } j \neq i \\ \varphi_i(g^{-1}) & \text{if } j = i. \end{cases}$$

This proves  $\chi_j(zg^{-1}) = \chi_i(g^{-1})\delta_{ij}$ , where  $\delta_{ij}$  is zero if  $i \neq j$  and is 1 if  $i = j$  (called the Kronecker delta). Substituting this into equation (13) gives  $\alpha_g = \frac{1}{|G|}\chi_i(1)\chi_i(g^{-1})$ . This is the coefficient of  $g$  in the statement of the proposition, completing the proof.

The orthonormality of the irreducible characters will follow directly from the orthogonality of the central primitive idempotents via the following calculation:

$$\begin{aligned} z_i\delta_{ij} &= z_iz_j \\ &= \frac{\chi_i(1)}{|G|} \frac{\chi_j(1)}{|G|} \sum_{g,h \in G} \chi_i(g^{-1})\chi_j(h^{-1})gh \\ &= \frac{\chi_i(1)}{|G|} \frac{\chi_j(1)}{|G|} \sum_{y \in G} \left[ \sum_{x \in G} \chi_i(xy^{-1})\chi_j(x^{-1}) \right] y \end{aligned}$$

(to get the latter sum from the former substitute  $y$  for  $gh$  and  $x$  for  $h$ ). Since the elements of  $G$  are a basis of  $\mathbb{C}G$  we may equate coefficients with those of  $z_i$  found in Proposition 13 to get (the coefficient of  $g$ )

$$\delta_{ij} \frac{\chi_i(1)}{|G|} \chi_i(g^{-1}) = \frac{\chi_i(1)\chi_j(1)}{|G|^2} \sum_{x \in G} \chi_i(xg^{-1})\chi_j(x^{-1}).$$

Simplifying (and replacing  $g$  by  $g^{-1}$ ) gives

$$\delta_{ij} \frac{\chi_i(g)}{\chi_j(1)} = \frac{1}{|G|} \sum_{x \in G} \chi_i(xg)\chi_j(x^{-1}) \quad \text{for all } g \in G. \quad (18.14)$$

Taking  $g = 1$  in (14) gives

$$\delta_{ij} = \frac{1}{|G|} \sum_{x \in G} \chi_i(x)\chi_j(x^{-1}). \quad (18.15)$$

The sum on the right side would be precisely the inner product  $(\chi_i, \chi_j)$  if  $\chi_j(x^{-1})$  were equal to  $\overline{\chi_j(x)}$ ; this is the content of the next proposition.

**Proposition 14.** If  $\psi$  is any character of  $G$  then  $\psi(x)$  is a sum of roots of 1 in  $\mathbb{C}$  and  $\psi(x^{-1}) = \overline{\psi(x)}$  for all  $x \in G$ .

*Proof:* Let  $\varphi$  be a representation whose character is  $\psi$ , fix an element  $x \in G$  and let  $|x| = k$ . Since the minimal polynomial of  $\varphi(x)$  divides  $X^k - 1$  (hence has distinct roots), there is a basis of the underlying vector space such that the matrix of  $\varphi(x)$  with respect to this basis is a diagonal matrix with  $k^{\text{th}}$  roots of 1 on the diagonal. Since  $\psi(x)$  is the sum of the diagonal entries (and does not depend on the choice of basis),  $\psi(x)$  is a sum of roots of 1. Moreover, if  $\epsilon$  is a root of 1,  $\epsilon^{-1} = \bar{\epsilon}$ . Thus the inverse of a diagonal matrix with roots of 1 on the diagonal is the diagonal matrix with the complex conjugates of those roots of 1 on the diagonal. Since the complex conjugate of a sum is the sum of the complex conjugates,  $\psi(x^{-1}) = \text{tr } \varphi(x^{-1}) = \overline{\text{tr } \varphi(x)} = \overline{\psi(x)}$ .

Keep in mind that in the proof of Proposition 14 we first fixed a group element  $x$  and then chose a basis of the representation space so that  $\varphi(x)$  was a diagonal matrix. It is always possible to diagonalize a single element but it is possible to *simultaneously* diagonalize all  $\varphi(x)$ 's if and only if  $\varphi$  is similar to a sum of degree 1 representations.

Combining the above proposition with equation (15) proves:

**Theorem 15. (The First Orthogonality Relation for Group Characters)** Let  $G$  be a finite group and let  $\chi_1, \dots, \chi_r$  be the irreducible characters of  $G$  over  $\mathbb{C}$ . Then with respect to the inner product  $(\cdot, \cdot)$  above we have

$$(\chi_i, \chi_j) = \delta_{ij}$$

and the irreducible characters are an orthonormal basis for the space of class functions. In particular, if  $\theta$  is any class function then

$$\theta = \sum_{i=1}^r (\theta, \chi_i) \chi_i.$$

*Proof:* We have just established that the irreducible characters form an orthonormal basis for the space of class functions. If  $\theta$  is any class function, write  $\theta = \sum_{i=1}^r a_i \chi_i$ , for some  $a_i \in \mathbb{C}$ . It follows from linearity of the Hermitian product that  $a_i = (\theta, \chi_i)$ , as stated.

We list without proof the Second Orthogonality Relation; we shall not require it for the applications in this book.

**Theorem 16. (The Second Orthogonality Relation for Group Characters)** Under the notation above, for any  $x, y \in G$

$$\sum_{i=1}^r \chi_i(x) \overline{\chi_i(y)} = \begin{cases} |C_G(x)| & \text{if } x \text{ and } y \text{ are conjugate in } G \\ 0 & \text{otherwise.} \end{cases}$$

**Definition.** For  $\theta$  any class function on  $G$  the *norm* of  $\theta$  is  $(\theta, \theta)^{1/2}$  and will be denoted by  $\|\theta\|$ .

When a class function is written in terms of the irreducible characters,  $\theta = \sum \alpha_i \chi_i$ , its norm is easily calculated as  $\|\theta\| = (\sum \alpha_i^2)^{1/2}$ . It follows that

*a character has norm 1 if and only if it is irreducible.*

Finally, observe that computations of the inner product of characters  $\theta$  and  $\psi$  may be simplified as follows. If  $\mathcal{K}_1, \dots, \mathcal{K}_r$  are the conjugacy classes of  $G$  with sizes  $d_1, \dots, d_r$  and representatives  $g_1, \dots, g_r$  respectively, then the value  $\theta(g_i)\overline{\psi(g_i)}$  appears  $d_i$  times in the sum for  $(\theta, \psi)$ , once for each element of  $\mathcal{K}_i$ . Collecting these terms gives

$$(\theta, \psi) = \frac{1}{|G|} \sum_{i=1}^r d_i \theta(g_i) \overline{\psi(g_i)},$$

a sum only over representatives of the conjugacy classes of  $G$ . In particular, the norm of  $\theta$  is given by

$$\|\theta\|^2 = (\theta, \theta) = \frac{1}{|G|} \sum_{i=1}^r d_i |\theta(g_i)|^2.$$

### Examples

- (1) Let  $G = S_3$  and let  $\pi$  be the permutation character of degree 3 described in the examples at the beginning of this section. Recall that  $\pi(\sigma)$  equals the number of elements in  $\{1, 2, 3\}$  fixed by  $\sigma$ . The conjugacy classes of  $S_3$  are represented by 1,  $(1 \ 2)$  and  $(1 \ 2 \ 3)$  of sizes 1, 3 and 2 respectively, and  $\pi(1) = 3$ ,  $\pi((1 \ 2)) = 1$ ,  $\pi((1 \ 2 \ 3)) = 0$ . Hence

$$\begin{aligned} \|\pi\|^2 &= \frac{1}{6} [1 \pi(1)^2 + 3 \pi((1 \ 2))^2 + 2 \pi((1 \ 2 \ 3))^2] \\ &= \frac{1}{6}(9 + 3 + 0) = 2 \end{aligned}$$

This implies that  $\pi$  is a sum of two distinct irreducible characters, each appearing with multiplicity 1. Let  $\chi_1$  be the principal character of  $S_3$ , so that  $\chi_1(\sigma) = \overline{\chi_1(\sigma)} = 1$  for all  $\sigma \in S_3$ . Then

$$\begin{aligned} (\pi, \chi_1) &= \frac{1}{6} [1 \pi(1) \overline{\chi_1(1)} + 3 \pi((1 \ 2)) \overline{\chi_1((1 \ 2))} + 2 \pi((1 \ 2 \ 3)) \overline{\chi_1((1 \ 2 \ 3))}] \\ &= \frac{1}{6}(3 + 3 + 0) = 1 \end{aligned}$$

so the principal character appears as a constituent of  $\pi$  with multiplicity 1. This proves  $\pi = \chi_1 + \chi_2$  for some irreducible character  $\chi_2$  of  $S_3$  of degree 2 (and agrees with our earlier decomposition of this representation). This also shows that the value of  $\chi_2$  on  $\sigma \in S_3$  is the number of fixed points of  $\sigma$  minus 1.

- (2) Let  $G = S_4$  and let  $\pi$  be the natural permutation character of degree 4 (so again  $\pi(\sigma)$  is the number of fixed points of  $\sigma$ ). The conjugacy classes of  $S_4$  are represented by 1,  $(1 \ 2)$ ,  $(1 \ 2 \ 3)$ ,  $(1 \ 2 \ 3 \ 4)$  and  $(1 \ 2)(3 \ 4)$  of sizes 1, 6, 8, 6 and 3 respectively. Again we compute:

$$\begin{aligned} \|\pi\|^2 &= \frac{1}{24} [1 \pi(1)^2 + 6 \pi((1 \ 2))^2 + 8 \pi((1 \ 2 \ 3))^2 + 6 \pi((1 \ 2 \ 3 \ 4))^2 \\ &\quad + 3 \pi((1 \ 2)(3 \ 4))^2] \\ &= \frac{1}{24}(16 + 24 + 8 + 0 + 0) = 2. \end{aligned}$$

so  $\pi$  has two distinct irreducible constituents. If  $\chi_1$  is the principal character of  $S_4$ , then

$$\begin{aligned} (\pi, \chi_1) &= \frac{1}{24} [1\pi(1) + 6\pi((1\ 2)) + 8\pi((1\ 2\ 3)) \\ &\quad + 6\pi((1\ 2\ 3\ 4)) + 3\pi((1\ 2)(3\ 4))] \\ &= \frac{1}{24}(4 + 12 + 8 + 0 + 0) = 1. \end{aligned}$$

This proves that the degree 4 permutation character is the sum of the principal character and an irreducible character of degree 3.

(3) Let  $G = D_8$ , where

$$D_8 = \langle r, s \mid s^2 = r^4 = 1, rs = sr^{-1} \rangle.$$

The conjugacy classes of  $D_8$  are represented by  $1, s, r, r^2$  and  $sr$  and have sizes 1, 2, 2, 1 and 2, respectively. Let  $\varphi$  be the degree 2 matrix representation of  $D_8$  obtained as in Example 6 in Section 1 from embedding a square in  $\mathbb{R}^2$ :

$$\varphi(s) = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \varphi(r) = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \varphi(r^2) = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}, \varphi(sr) = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

Let  $\psi$  be the character of this representation (where we consider the real matrices as a subset of the complex matrices). Again, since  $\psi$  is real valued one computes

$$\begin{aligned} \|\psi\|^2 &= \frac{1}{8} [1\psi(1)^2 + 2\psi(s)^2 + 2\psi(r)^2 + 1\psi(r^2)^2 + 2\psi(sr)^2] \\ &= \frac{1}{8}(4 + 0 + 0 + 4 + 0) = 1. \end{aligned}$$

This proves the representation  $\varphi$  is irreducible (even if we allow similarity transformations by complex matrices).

We have seen that the sum of two characters is again a character. Specifically, if  $\psi_1$  and  $\psi_2$  are characters of representations  $\varphi_1$  and  $\varphi_2$ , then  $\psi_1 + \psi_2$  is the character of  $\varphi_1 + \varphi_2$ .

**Proposition 17.** If  $\psi_1$  and  $\psi_2$  are characters, then so is their product  $\psi_1\psi_2$ .

*Proof:* Let  $V_1$  and  $V_2$  be  $\mathbb{C}G$ -modules affording characters  $\psi_1$  and  $\psi_2$  and define  $W = V_1 \otimes_{\mathbb{C}} V_2$ . Since each  $g \in G$  acts as a linear transformation on  $V_1$  and  $V_2$ , the action of  $g$  on simple tensors by  $g(v_1 \otimes v_2) = (gv_1) \otimes (gv_2)$  extends by linearity to a well defined linear transformation on  $W$  by Proposition 17 in Section 11.2. One easily checks that this action also makes  $W$  into a  $\mathbb{C}G$ -module. By Exercise 38 in Section 11.2 the character afforded by  $W$  is  $\psi_1\psi_2$ .

The next chapter will contain further explicit character computations as well as some applications of group characters to proving theorems about certain classes of groups.

## Some Remarks on Fourier Analysis and Group Characters

This brief discussion is intended to indicate some connections of the results above with other areas of mathematics.

The theory of group representations described to this point is a special branch of an area of mathematics called Harmonic Analysis. Readers may already be familiar with the basic theory of Fourier series which also falls into this realm. We make some observations which show how representation theory for finite groups corresponds to “Fourier series” for some infinite groups (in particular, to Fourier series on the circle). To be mathematically precise one needs the Lebesgue integral to ensure completeness of certain (Hilbert) spaces but readers may get the flavor of things by replacing “Lebesgue” by “Riemann.”

Let  $G$  be the multiplicative group of points on the unit circle in  $\mathbb{C}$ :

$$G = \{z \in \mathbb{C} \mid |z| = 1\}.$$

We shall usually view  $G$  as the interval  $[0, 2\pi]$  in  $\mathbb{R}$  with the two end points identified, i.e., as the additive group  $\mathbb{R}/2\pi\mathbb{Z}$  (the isomorphism is: the real number  $x$  corresponds to the complex number  $e^{ix}$ ). Note that  $G$  has a translation invariant measure, namely the Lebesgue measure, and the measure of the circle is  $2\pi$ . For finite groups, the counting measure is the translation invariant measure (so the measure of a subset  $H$  is the number of elements in that subset,  $|H|$ ) and integrals on a finite group with respect to this counting measure are just finite sums.

The space

$$L^2(G) = \{f : G \rightarrow \mathbb{C} \mid f \text{ is measurable and } |f|^2 \text{ is integrable over } G\}$$

plays the role of the group algebra of the infinite group  $G$ . This space becomes a commutative ring with 1 under the convolution of functions: for  $f, g \in L^2(G)$  the product  $f * g : G \rightarrow \mathbb{C}$  is defined by

$$(f * g)(x) = \frac{1}{2\pi} \int_0^{2\pi} f(x - y)g(y) dy \quad \text{for all } x \in G.$$

(Recall that for a finite group  $H$ , the group algebra is also formally the ring of  $\mathbb{C}$ -valued functions on  $H$  under a convolution multiplication and that these functions are written as formal sums – the element  $\sum \alpha_g g \in \mathbb{C}G$  denotes the function which sends  $g$  to  $\alpha_g \in \mathbb{C}$  for all  $g \in G$ .)

The complete set of continuous homomorphisms of  $G$  into  $GL_1(\mathbb{C})$  is given by

$$e_n(x) = e^{inx}, \quad x \in [0, 2\pi], \quad n \in \mathbb{Z}.$$

(Recall that for a finite abelian group, all irreducible representations are 1-dimensional and for 1-dimensional representations, characters and representations may be identified.)

The ring  $L^2(G)$  admits an Hermitian inner product: for  $f, g \in L^2(G)$

$$(f, g) = \frac{1}{2\pi} \int_0^{2\pi} f(t)\overline{g(t)} dt.$$

Under this inner product,  $\{e_n \mid n \in \mathbb{Z}\}$  is an orthonormal basis (where the term “basis” is used in the analytic sense that these are independent and 0 is the only function orthogonal to all of them). Moreover,

$$L^2(G) = \widehat{\bigoplus_{n \in \mathbb{Z}} E_n}$$

where  $E_n$  is the 1-dimensional subspace spanned by  $e_n$ , the hat over the direct sum denotes taking the closure of the direct sum in the  $L^2$ -topology, and equality indicates equality in the  $L^2$  sense. (Recall that the group algebra of a finite abelian group is the direct sum of the irreducible 1-dimensional submodules, each occurring with multiplicity one.) These facts imply the well known result from Fourier analysis that every square integrable function  $f(x)$  on  $[0, 2\pi]$  has a Fourier series

$$\sum_{n=-\infty}^{\infty} c_n e^{inx}$$

where the Fourier coefficients,  $c_n$ , are given by

$$c_n = (f, e_n) = \frac{1}{2\pi} \int_0^{2\pi} f(t) e^{-int} dt.$$

This brief description indicates how the representation theory of finite groups extends to certain infinite groups and the results we have proved may already be familiar in the latter context. In fact, there is a completely analogous theory for arbitrary (not necessarily abelian) compact Lie groups — here the irreducible (complex) representations need not be 1-dimensional but they are all finite dimensional and  $L^2(G)$  decomposes as a direct sum of them, each appearing with multiplicity equal to its degree. The emphasis (at least at the introductory level) in this theory is often on the importance of being able to represent functions as (Fourier) series and then using these series to solve other problems (e.g., solve differential equations). The underlying group provides the “symmetry” on which to build this “harmonic analysis,” rather than being itself the principal object of study.

## EXERCISES

Let  $G$  be a finite group. Unless stated otherwise all representations and characters are over  $\mathbb{C}$ .

1. Prove that  $\text{tr } AB = \text{tr } BA$  for  $n \times n$  matrices  $A$  and  $B$  with entries from any commutative ring.
2. In each of (a) to (c) let  $\psi$  be the character afforded by the specified representation  $\varphi$ .
  - (a) Let  $\varphi$  be the degree 2 representation of  $D_{10}$  described in Example 6 in the second set of examples in Section 1 (here  $n = 5$ ) and show that  $\|\psi\|^2 = 1$  (hence  $\varphi$  is irreducible).
  - (b) Let  $\varphi$  be the degree 2 representation of  $Q_8$  described in Example 7 in the second set of examples in Section 1 and show that  $\|\psi\|^2 = 1$  (hence  $\varphi$  is irreducible).
  - (c) Let  $\varphi$  be the degree 4 representation of  $Q_8$  described in Example 8 in the second set of examples in Section 1 and show that  $\|\psi\|^2 = 4$  (hence even though  $\varphi$  is irreducible over  $\mathbb{R}$ ,  $\varphi$  decomposes over  $\mathbb{C}$  as twice an irreducible representation of degree 2).
3. If  $\chi$  is an irreducible character of  $G$ , prove that the  $\chi$ -isotypic subspace of a  $\mathbb{C}G$ -module is unique.

4. Prove that if  $N$  is any irreducible  $\mathbb{C}G$ -module and  $M = N \oplus N$ , then  $M$  has infinitely many direct sum decompositions into two copies of  $N$ .
5. Prove that a class function is a character if and only if it is a positive integral linear combination of irreducible characters.
6. Let  $\varphi : G \rightarrow GL(V)$  be a representation with character  $\psi$ . Let  $W$  be the subspace  $\{v \in V \mid \varphi(g)(v) = v \text{ for all } g \in G\}$  of  $V$  fixed pointwise by all elements of  $G$ . Prove that  $\dim W = (\psi, \chi_1)$ , where  $\chi_1$  is the principal character of  $G$ .
7. Assume  $V$  is a  $\mathbb{C}G$ -module on which  $G$  acts by permuting the basis  $\mathcal{B} = \{e_1, \dots, e_n\}$ . Write  $\mathcal{B}$  as a disjoint union of the orbits  $\mathcal{B}_1, \dots, \mathcal{B}_t$  of  $G$  on  $\mathcal{B}$ .
  - (a) Prove that  $V$  decomposes as a  $\mathbb{C}G$ -module as  $V_1 \oplus \dots \oplus V_t$ , where  $V_i$  is the span of  $\mathcal{B}_i$ .
  - (b) Prove that if  $v_i$  is the sum of the vectors in  $\mathcal{B}_i$  then the 1-dimensional subspace of  $V_i$  spanned by  $v_i$  is the unique  $\mathbb{C}G$ -submodule of  $V_i$  affording the trivial representation (in other words, any vector in  $V_i$  that is fixed under the action of  $G$  is a multiple of  $v_i$ ). [Use the fact that  $G$  is transitive on  $\mathcal{B}_i$ . See also Exercise 8 in Section 1.]
  - (c) Let  $W = \{v \in V \mid \varphi(g)(v) = v \text{ for all } g \in G\}$  be the subspace of  $V$  fixed pointwise by all elements of  $G$ . Deduce that  $\dim W = t =$  the number of orbits of  $G$  on  $\mathcal{B}$ .
8. Prove the following result (sometimes called Burnside's Lemma although its origin is with Frobenius): let  $G$  be a subgroup of  $S_n$  and for each  $\sigma \in G$  let  $\text{Fix}(\sigma)$  denote the number of fixed points of  $\sigma$  on  $\{1, \dots, n\}$ . Let  $t$  be the number of orbits of  $G$  on  $\{1, \dots, n\}$ . Then

$$t|G| = \sum_{g \in G} \text{Fix}(g).$$

[Use the preceding two exercises.]

9. Let  $G$  be a nontrivial, transitive group of permutations on the finite set  $\Omega$  and let  $\psi$  be the character afforded by the linear representation over  $\mathbb{C}$  obtained from  $\Omega$  (cf. Example 4 in Section 1) so  $\psi(\sigma)$  is the number of fixed points of  $\sigma$  on  $\Omega$ . Now let  $G$  act on the set  $\Omega \times \Omega$  by  $g \cdot (\omega_1, \omega_2) = (g \cdot \omega_1, g \cdot \omega_2)$  and let  $\pi$  be the character afforded by the linear representation obtained from this action.
  - (a) Prove that  $\pi = \psi^2$ .
  - (b) Prove that the number of orbits of  $G$  on  $\Omega \times \Omega$  is given by the inner product  $(\psi, \psi)$ . [By the preceding exercises, the number of orbits on  $\Omega \times \Omega$  is equal to  $(\pi, \chi_1)$ , where  $\chi_1$  is the principal character.]
  - (c) Recall that  $G$  is said to be *doubly transitive* on  $\Omega$  if it has precisely 2 orbits in its action on  $\Omega \times \Omega$  (it always has at least 2 orbits since the diagonal,  $\{(\omega, \omega) \mid \omega \in \Omega\}$ , is one orbit). Prove that if  $G$  is doubly transitive on  $\Omega$  then  $\psi = \chi_1 + \chi_2$ , where  $\chi_1$  is the principal character and  $\chi_2$  is a nonprincipal irreducible character of  $G$ .
  - (d) Let  $\Omega = \{1, 2, \dots, n\}$  and let  $G = S_n$  act on  $\Omega$  in the natural fashion. Show that the character of the associated linear representation decomposes as the principal character plus an irreducible character of degree  $n - 1$ .
10. Let  $\psi$  be the character of any 2-dimensional representation of a group  $G$  and let  $x$  be an element of order 2 in  $G$ . Prove that  $\psi(x) = 2, 0$  or  $-2$ . Generalize this to  $n$ -dimensional representations.
11. Let  $\chi$  be an irreducible character of  $G$ . Prove that for every element  $z$  in the center of  $G$  we have  $\chi(z) = \epsilon \chi(1)$ , where  $\epsilon$  is some root of 1 in  $\mathbb{C}$ . [Use Schur's Lemma.]
12. Let  $\psi$  be the character of some representation  $\varphi$  of  $G$ . Prove that for  $g \in G$  the following hold:
  - (a) if  $\psi(g) = \psi(1)$  then  $g \in \ker \varphi$ , and

- (b) if  $|\psi(g)| = \psi(1)$  and  $\varphi$  is faithful then  $g \in Z(G)$  (where  $|\psi(g)|$  is the complex absolute value of  $\psi(g)$ ). [Use the method of proof of Proposition 14.]

- 13.** Let  $\varphi : G \rightarrow GL(V)$  be a representation and let  $\chi : G \rightarrow \mathbb{C}^\times$  be a degree 1 representation. Prove that  $\chi\varphi : G \rightarrow GL(V)$  defined by  $\chi\varphi(g) = \chi(g)\varphi(g)$  is a representation (note that multiplication of the linear transformation  $\varphi(g)$  by the complex number  $\chi(g)$  is well defined). Show that  $\chi\varphi$  is irreducible if and only if  $\varphi$  is irreducible. Show that if  $\psi$  is the character afforded by  $\varphi$  then  $\chi\psi$  is the character afforded by  $\chi\varphi$ . Deduce that the product of any irreducible character with a character of degree 1 is also an irreducible character.

The next few exercises study the notion of *algebraically conjugate* characters. These exercises may be considered as extensions of Proposition 14 and some consequences of these extensions. In particular we obtain a group-theoretic characterization of the conditions under which all irreducible characters of a group take values in  $\mathbb{Q}$ .

Let  $F$  be the subfield of  $\mathbb{C}$  of all elements that are algebraic over  $\mathbb{Q}$  (the field of algebraic numbers). Thus  $F$  is the algebraic closure of  $\mathbb{Q}$  contained in  $\mathbb{C}$  and all the results established over  $\mathbb{C}$  hold without change over  $F$ .

- 14.** Note that since  $F \subseteq \mathbb{C}$ , every representation  $\varphi : G \rightarrow GL_m(F)$  may also be considered as a complex representation. Prove that if  $\varphi$  is a representation over  $F$  that is irreducible over  $F$ , then  $\varphi$  is also irreducible when considered over the larger field  $\mathbb{C}$  (note that this is not true if  $F$  is not algebraically closed — cf. Exercise 2(c) above). Show that the set of irreducible characters of  $G$  over  $F$  is the same as the set of irreducible characters over  $\mathbb{C}$  (i.e., these are exactly the same set of class functions on  $G$ ). Deduce that every complex representation is equivalent to a representation over  $F$ . [Since  $F$  is algebraically closed of characteristic 0, the irreducible characters over either  $F$  or  $\mathbb{C}$  are characterized by the first orthogonality relation.]

Let  $\varphi : G \rightarrow GL_m(F)$  be any representation with character  $\psi$ . Let  $\mathbb{Q}(\varphi)$  denote the subfield of  $F$  generated by all the entries of the matrices  $\varphi(g)$  for all  $g \in G$ .

- 15.** Prove that  $\mathbb{Q}(\varphi)$  is a finite extension of  $\mathbb{Q}$ .

Now let  $K$  be any Galois extension of  $\mathbb{Q}$  containing  $\mathbb{Q}(\varphi)$  and let  $\sigma \in \text{Gal}(K/\mathbb{Q})$ . In fact, since every automorphism of  $K$  extends to an automorphism of  $F$ , we may assume  $\sigma$  is any automorphism of  $F$ . The map  $\varphi^\sigma : G \rightarrow GL_n(F)$  is defined by letting  $\varphi^\sigma(g)$  be the  $n \times n$  matrix whose entries are obtained by applying the field automorphism  $\sigma$  to the entries of the matrix  $\varphi(g)$ .

- 16.** Prove that  $\varphi^\sigma$  is a representation. Prove also that the character of  $\varphi^\sigma$  is  $\psi^\sigma$ , where  $\psi^\sigma(g) = \sigma(\psi(g))$ .

- 17.** Prove that  $\varphi$  is irreducible if and only if  $\varphi^\sigma$  is irreducible.

The representation  $\varphi^\sigma$  (or character  $\psi^\sigma$ ) is called the *algebraic conjugate* of  $\varphi$  by  $\sigma$  (or of  $\psi$ , respectively); two representations  $\varphi_1$  and  $\varphi_2$  (or characters  $\psi_1$  and  $\psi_2$ ) are said to be *algebraically conjugate* if there is some automorphism  $\sigma$  of  $F$  such that  $\varphi_1^\sigma = \varphi_2$  (or  $\psi_1^\sigma = \psi_2$ , respectively). Some care needs to be taken with this (standard) notation since the exponential notation usually denotes a right action whereas automorphisms of  $F$  act on the left on representations:  $\varphi^{(\sigma\tau)} = (\varphi^\tau)^\sigma$ .

Let  $\mathbb{Q}(\psi)$  be the subfield of  $F$  generated by the numbers  $\psi(g)$  for all  $g \in G$ . Let  $|G| = n$  and let  $\epsilon$  be a primitive  $n^{\text{th}}$  root of 1 in  $F$ .

- 18.** Prove that  $\mathbb{Q}(\psi) \subseteq \mathbb{Q}(\epsilon)$ . Deduce that  $\mathbb{Q}(\psi)$  is a Galois extension of  $\mathbb{Q}$  with abelian Galois group. [See Proposition 14.]

Recall from Section 14.5 that  $\text{Gal}(\mathbb{Q}(\epsilon)/\mathbb{Q}) \cong (\mathbb{Z}/n\mathbb{Z})^\times$ , where the Galois automorphisms are given on the generator  $\epsilon$  by  $\sigma_a : \epsilon \mapsto \epsilon^a$ , where  $a$  is an integer relatively prime to  $n$ .

19. Prove that if  $\sigma_a \in \text{Gal}(\mathbb{Q}(\epsilon)/\mathbb{Q})$  is the field automorphism defined above, then for all  $g \in G$  we have  $\psi^{\sigma_a}(g) = \psi(g^a)$ . [Use the method of Proposition 14.]
20. Prove that if  $g$  is an element of  $G$  which is conjugate to  $g^a$  for all integers  $a$  relatively prime to  $n$ , then  $\psi(g) \in \mathbb{Q}$ , for every character  $\psi$  of  $G$ . [Use the preceding exercise and the fact that  $\mathbb{Q}$  is the field fixed by all  $\sigma_a$ 's.]
21. Prove that an element  $g \in G$  is conjugate to  $g^a$  for all integers  $a$  relatively prime to  $|G|$  if and only if  $g$  is conjugate to  $g^{a'}$  for all integers  $a'$  relatively prime to  $|g|$ .
22. Show for any positive integer  $n$  that every character of the symmetric group  $S_n$  is rational valued (i.e.,  $\psi(g) \in \mathbb{Q}$  for all  $g \in S_n$  and all characters  $\psi$  of  $S_n$ ).

The next two exercises establish the converse to Exercise 20.

23. Prove that elements  $x$  and  $y$  are conjugate in a group  $G$  if and only if  $\chi(x) = \chi(y)$  for all irreducible characters  $\chi$  of  $G$ .
24. Let  $g \in G$  and assume that every irreducible character of  $G$  is rational valued on  $g$ . Prove that  $g$  is conjugate to  $g^a$  for every integer  $a$  relatively prime to  $|G|$ . [If  $g$  is not conjugate to  $g^a$  for some  $a$  relatively prime to  $|G|$  then by the preceding exercise there is an irreducible character  $\chi$  such that  $\chi(g) \neq \chi(g^a)$ . Derive a contradiction from the hypothesis that  $\chi(g) \in \mathbb{Q}$ .]
25. Describe which irreducible characters of the cyclic group of order  $n$  are algebraically conjugate.
26. Prove that every irreducible character of both  $Q_8$  and  $D_8$  is rational valued. Prove that  $D_{10}$  has an irreducible character that is not rational valued.
27. Let  $G = H \times K$  and let  $\varphi : H \rightarrow GL(V)$  be an irreducible representation of  $H$  with character  $\chi$ . Then  $G \xrightarrow{\pi_H} H \xrightarrow{\varphi} GL(V)$  gives an irreducible representation of  $G$ , where  $\pi_H$  is the natural projection; the character,  $\tilde{\chi}$ , of this representation is  $\tilde{\chi}((h, k)) = \chi(h)$ . Likewise any irreducible character  $\psi$  of  $K$  gives an irreducible character  $\tilde{\psi}$  of  $G$  with  $\tilde{\psi}((h, k)) = \psi(k)$ .
  - (a) Prove that the product  $\tilde{\chi}\tilde{\psi}$  is an irreducible character of  $G$ . [Show it has norm 1.]
  - (b) Prove that every irreducible character of  $G$  is obtained from such products of irreducible characters of the direct factors. [Use Theorem 10, either (3) or (4).]
28. (*Finite subgroups of  $GL_2(\mathbb{Q})$* ) Let  $G$  be a finite subgroup of  $GL_2(\mathbb{Q})$ .
  - (a) Show that  $GL_2(\mathbb{Q})$  does not contain an element of order  $n$  for  $n = 5, 7$ , or  $n \geq 9$ . Deduce that  $|G| = 2^a 3^b$ . [Use rational canonical forms.]
  - (b) Show that the Klein 4-group is the only noncyclic abelian subgroup of  $GL_2(\mathbb{Q})$ . Deduce from this and (a) that  $|G| \mid 24$ .
  - (c) Show that the only finite subgroups of  $GL_2(\mathbb{Q})$  are the cyclic groups of order 1, 2, 3, 4, and 6, the Klein 4-group, and the dihedral groups of order 6, 8, and 12. [Use the classifications of groups of small order in Section 4.5 and Exercise 10 of Section 1 to restrict  $G$  to this list. Show conversely that each group listed has a 2-dimensional faithful rational representation.]

# CHAPTER 19

## Examples and Applications of Character Theory

### 19.1 CHARACTERS OF GROUPS OF SMALL ORDER

The *character table* of a finite group is the table of character values formatted as follows: list representatives of the  $r$  conjugacy classes along the top row and list the irreducible characters down the first column. The entry in the table in row  $\chi_i$  and column  $g_j$  is  $\chi_i(g_j)$ . The character table of a finite group is unique up to a permutation of its rows and columns. It is customary to make the principal character the first row and the identity the first column and to list the characters in increasing order by degrees. In our examples we shall list the size of the conjugacy classes under each class so the entire table will have  $r + 2$  rows and  $r + 1$  columns (although strictly speaking, the character table is the  $r \times r$  matrix of character values). This will enable one to easily check the “orthogonality of rows” using the first orthogonality relation: if the classes are represented by  $g_1, \dots, g_r$  of sizes  $d_1, \dots, d_r$ , then

$$(\chi_i, \chi_j) = \frac{1}{|G|} \sum_{k=1}^r d_k \chi_i(g_k) \overline{\chi_j(g_k)}.$$

The second orthogonality relation says that the Hermitian product of any two distinct columns of a character table is zero (i.e., it gives an “orthogonality of columns”).

A number of character tables are given in the *Atlas of Finite Groups* by Conway, Curtis, Norton, Parker and Wilson, Clarendon Press, 1985. These include the character table of the Monster simple group,  $M$ . The group  $M$  has 194 irreducible characters. The smallest degree of a nonprincipal irreducible character of  $M$  is 196883 and the largest degree is on the order of  $2 \times 10^{26}$ . Nonetheless, it is possible to compute the values of all these characters on all conjugacy classes of  $M$ .

For the first example of a character table let  $G = \langle x \rangle$  be the cyclic group of order 2. Then  $G$  has 2 conjugacy classes and two irreducible characters:

classes:	1	$x$
sizes:	1	1
$\chi_1$	1	1
$\chi_2$	1	-1

Character Table of  $Z_2$

The characters and representations of this abelian group are the same, and the irreducible representations of any abelian group are described in Example 1 at the end of Section 18.2.

Similarly, if  $G = \langle x \rangle$  is cyclic of order 3, and  $\zeta$  is a fixed primitive cube root of 1 (so  $\zeta^2 = \bar{\zeta}$ ), then the character table of  $G$  is the following:

classes: sizes:	1	$x$	$x^2$
	1	1	1
$\chi_1$	1	1	1
$\chi_2$	1	$\zeta$	$\zeta^2$
$\chi_3$	1	$\zeta^2$	$\zeta$

**Character Table of  $Z_3$**

Next we construct the character table of  $S_3$ . Recall from Example 2 in Section 18.2 that  $S_3$  has 3 irreducible characters whose values are described in that example and in Example 1 at the end of Section 18.3.

classes: sizes:	1	(1 2)	(1 2 3)
	1	3	2
$\chi_1$	1	1	1
$\chi_2$	1	-1	1
$\chi_3$	2	0	-1

**Character Table of  $S_3$**

Next we consider  $D_8$ , adopting the notation of Example 3 of Section 18.3. By Corollary 11,  $D_8$  has four characters of degree 1. Also, in Example 3 we constructed an irreducible degree 2 representation. Since the sum of the squares of the degrees of these representations is 8, this accounts for all irreducible representations (or, since there are 5 conjugacy classes, there are 5 irreducible representations). If we let bars denote passage to the commutator quotient group (which is the Klein 4-group), then  $\bar{1} = \bar{r^2}$ . The degree 1 representations (= their characters) are computed by sending generators  $\bar{s}$  and  $\bar{r}$  to  $\pm 1$  (and the product class is mapped to the product of the values). Matrices for the degree 2 irreducible representation were computed in Example 3 of Section 18.3 and the character of this representation can be read directly from these matrices. The character table of  $D_8$  is therefore the following:

classes: sizes:	1	$r^2$	$s$	$r$	$sr$
	1	1	2	2	2
$\chi_1$	1	1	1	1	1
$\chi_2$	1	1	-1	1	-1
$\chi_3$	1	1	1	-1	-1
$\chi_4$	1	1	-1	-1	1
$\chi_5$	2	-2	0	0	0

**Character Table of  $D_8$**

Now we compute the character table of the quaternion group of order 8. We use the usual presentation

$$Q_8 = \langle i, j \mid i^4 = 1, i^2 = j^2, i^{-1}ji = j^{-1} \rangle$$

and let  $k = ij$  and  $i^2 = -1$ . The conjugacy classes of  $Q_8$  are represented by  $1, -1, i, j$  and  $k$  of sizes 1, 1, 2, 2 and 2, respectively. Since the commutator quotient of  $Q_8$  is the Klein 4-group, there are four characters of degree 1. The one remaining irreducible character must have degree 2 in order that the sum of the squares of the degrees be 8. Let  $\chi_5$  be the degree 2 irreducible character of  $Q_8$ . One may check that the representation  $\varphi : Q_8 \rightarrow GL_2(\mathbb{C})$  described explicitly in Example 7 in the second set of examples of Section 18.1 affords  $\chi_5$ , but we show how the orthogonality relations give the values of  $\chi_5$  without knowing these explicit matrices. If  $\varphi$  is an irreducible representation of degree 2, by Schur's Lemma (cf. Exercise 18 in Section 18.1)  $\varphi(-1)$  is a  $2 \times 2$  scalar matrix and so is  $\pm$  the identity matrix since  $-1$  has order 2 in  $Q_8$ . Hence  $\chi_5(-1) = \pm 2$ . Let  $\chi_5(i) = a, \chi_5(j) = b$  and  $\chi_5(k) = c$ . The orthogonality relations give

$$1 = (\chi_5, \chi_5) = \frac{1}{8}(2^2 + (\pm 2)^2 + 2a\bar{a} + 2b\bar{b} + 2c\bar{c}).$$

Since  $a\bar{a}, b\bar{b}$  and  $c\bar{c}$  are nonnegative real numbers, they must all be zero. Also, since  $\chi_5$  is orthogonal to the principal character we get

$$0 = (\chi_1, \chi_5) = \frac{1}{8}(2 + (\pm 2) + 0 + 0 + 0),$$

hence  $\chi_5(-1) = -2$ . The complete character table of  $Q_8$  is the following:

classes:	1	-1	$i$	$j$	$k$
sizes:	1	1	2	2	2
$\chi_1$	1	1	1	1	1
$\chi_2$	1	1	-1	1	-1
$\chi_3$	1	1	1	-1	-1
$\chi_4$	1	1	-1	-1	1
$\chi_5$	2	-2	0	0	0

### Character Table of $Q_8$

Observe that  $D_8$  and  $Q_8$  have the same character table, hence

*nonisomorphic groups may have the same character table.*

Note that the values of the degree 2 representation of  $Q_8$  could also have been easily calculated by applying the second orthogonality relation to each column of the character table. We leave this check as an exercise. Also note that although the degree 2 irreducible characters of  $D_8$  and  $Q_8$  have the same (real number) values the degree 2 representation of  $D_8$  may be realized by real matrices whereas it may be shown that  $Q_8$  has no faithful 2-dimensional representation over  $\mathbb{R}$  (cf. Exercise 10 in Section 18.1).

For the next example we construct the character table of  $S_4$ . The conjugacy classes of  $S_4$  are represented by  $1, (1 2), (1 2 3), (1 2 3 4)$  and  $(1 2)(3 4)$  with sizes 1, 6, 8, 6, and 3 respectively. Since  $S'_4 = A_4$ , there are two characters of degree 1: the principal character and the character whose values are the sign of the permutation.

To obtain a degree 2 irreducible character let  $V$  be the normal subgroup of order 4 generated by  $(1\ 2)(3\ 4)$  and  $(1\ 3)(2\ 4)$ . Any representation  $\varphi$  of  $S_4/V \cong S_3$  gives, by composition with the natural projection  $S_4 \rightarrow S_4/V$ , a representation of  $S_4$ ; if the former is irreducible, so is the latter. Let  $\varphi$  be the composition of the projection with the irreducible 2-dimensional representation of  $S_3$ , and let  $\chi_3$  be its character. The classes of 1 and  $(1\ 2)(3\ 4)$  map to the identity in the  $S_3$  quotient,  $(1\ 2)$  and  $(1\ 2\ 3\ 4)$  map to transpositions and  $(1\ 2\ 3)$  maps to a 3-cycle. The values of  $\chi_3$  can thus be read directly from the values of the character of degree 2 in the table for  $S_3$ .

Since  $S_4$  has 5 irreducible characters and the sum of the squares of the degrees is 24, there must be two remaining irreducible characters, each of degree 3. In Example 2 of Section 18.3 one of these was calculated, call it  $\chi_4$ . Recall that

$$\chi_4(\sigma) = (\text{the number of fixed points of } \sigma) - 1.$$

The remaining irreducible character,  $\chi_5$ , is  $\chi_4\chi_2$ . One can either use Proposition 17 in Section 18.3 or Exercise 13 in Section 18.3 to see that this product is indeed a character. The first orthogonality relation verifies that it is irreducible.

classes: sizes:	1	$(1\ 2)$	$(1\ 2\ 3)$	$(1\ 2\ 3\ 4)$	$(1\ 2)(3\ 4)$
$\chi_1$	1	1	1	1	1
$\chi_2$	1	-1	1	-1	1
$\chi_3$	2	0	-1	0	2
$\chi_4$	3	1	0	-1	-1
$\chi_5$	3	-1	0	1	-1

Character Table of  $S_4$

From the character table of  $S_4$  one can easily compute the character table of  $A_4$ . Note that  $A_4$  has 4 conjugacy classes. Also  $|A_4 : A'_4| = 3$ , so  $A_4$  has three characters of degree 1 with  $V = A'_4$  in the kernel of each degree 1 representation. The remaining irreducible character must have degree 3. One checks directly from the orthogonality relation applied in  $A_4$  that the character  $\chi_4$  of  $S_4$  restricted to  $A_4$  ( $= \chi_5|_{A_4}$ ) is irreducible. This irreducibility check is really necessary since an irreducible representation of a group need not restrict to an irreducible representation of a subgroup (for instance, the irreducible degree 2 representation of  $S_3$  must become reducible when restricted to any proper subgroup, since these are all abelian). The character table of  $A_4$  is the following

classes: sizes:	1	$(1\ 2)(3\ 4)$	$(1\ 2\ 3)$	$(1\ 3\ 2)$
$\chi_1$	1	1	1	1
$\chi_2$	1	1	$\zeta$	$\zeta^2$
$\chi_3$	1	1	$\zeta^2$	$\zeta$
$\chi_4$	3	-1	0	0

Character Table of  $A_4$

where  $\zeta$  is a primitive cube root of 1 in  $\mathbb{C}$ .

As a final example we construct the following character table of  $S_5$ :

classes: sizes:	1	(1 2)	(1 2 3)	(1 2 3 4)	(1 2 3 4 5)	(1 2)(3 4)	(1 2)(3 4 5)
	1	10	20	30	24	15	20
$\chi_1$	1	1	1	1	1	1	1
$\chi_2$	1	-1	1	-1	1	1	-1
$\chi_3$	4	2	1	0	-1	0	-1
$\chi_4$	4	-2	1	0	-1	0	1
$\chi_5$	5	-1	-1	1	0	1	-1
$\chi_6$	5	1	-1	-1	0	1	1
$\chi_7$	6	0	0	0	1	-2	0

### Character Table of $S_5$

The conjugacy classes and their sizes were computed in Section 4.3. Since  $|S_5 : S'_5| = 2$ , there are two degree 1 characters: the principal character and the “sign” character.

The natural permutation of  $S_5$  on 5 points gives rise to a permutation character of degree 5. As with  $S_4$  and  $S_3$  the orthogonality relations show that the square of its norm is 2 and it contains the principal character. Thus  $\chi_3$  is the permutation character minus the principal character (and, as with the smaller symmetric groups,  $\chi_3(\sigma)$  is the number of fixed points of  $\sigma$  minus 1). As argued with  $S_4$ , it follows that  $\chi_4 = \chi_3\chi_2$  is also an irreducible character.

To obtain  $\chi_5$  recall that  $S_5$  has six Sylow 5-subgroups. Its action by conjugation on these gives a faithful permutation representation of degree 6. If  $\psi$  is the character of the associated linear representation, then since  $\sigma \in S_5$  fixes a Sylow 5-subgroup if and only if it normalizes that subgroup, we have

$$\psi(\sigma) = \text{the number of Sylow 5-subgroups normalized by } \sigma.$$

The normalizer in  $S_5$  of the Sylow 5-subgroup  $(1 2 3 4 5)$  is  $(1 2 3 4 5), (2 3 5 4)$  and all normalizers of Sylow 5-subgroups are conjugate in  $S_5$  to this group. This normalizer contains only the identity, 5-cycles, 4-cycles and products of two disjoint transpositions. No other cycle type normalizes any Sylow 5-subgroup so on any other class,  $\psi$  is zero. To compute  $\psi$  on the remaining three nonidentity classes note (by inspection in  $S_6$ ) that in any faithful action on 6 points the following hold: an element of order 5 must be a 5-cycle (hence fixes 1 point); any element of order 4 which fixes one point must be a 4-cycle (hence fixes 2 points); an element of order 2 which is the square of an element of order 4 fixes exactly 2 points also. This gives all the values of  $\psi$ . Now direct computation shows that

$$\|\psi\|^2 = 2 \quad \text{and} \quad (\chi_1, \psi) = 1.$$

Thus  $\chi_5 = \psi - \chi_1$  is irreducible of degree 5. By the same theory as for  $\chi_4$  one gets that  $\chi_6 = \chi_5\chi_2$  is another irreducible character.

Since there are 7 conjugacy classes, there is one remaining irreducible character and its degree is 6. Its values can be obtained immediately from the decomposition of the regular character,  $\rho$  (cf. Example 3 in Section 18.2 and Example 4 in Section 18.3):

$$\chi_7 = \frac{\rho - \chi_1 - \chi_2 - 4\chi_3 - 4\chi_4 - 5\chi_5 - 5\chi_6}{6}.$$

A direct calculation by the orthogonality relations checks that  $\chi_7$  is irreducible. Note that the values of the character  $\chi_7$  were computed without explicitly exhibiting a representation with this character.

## EXERCISES

1. Calculate the character tables of  $Z_2 \times Z_2$ ,  $Z_2 \times Z_3$  and  $Z_2 \times Z_2 \times Z_2$ . Explain why the table of  $Z_2 \times Z_3$  contains primitive 6<sup>th</sup> roots of 1.
2. Compute the degrees of the irreducible characters of  $D_{16}$ .
3. Compute the degrees of the irreducible characters of  $A_5$ . Deduce that the degree 6 irreducible character of  $S_5$  is not irreducible when restricted to  $A_5$ . [The conjugacy classes of  $A_5$  are worked out in Section 4.3.]
4. Using the character tables in this section, for each of parts (a) to (d) use the first orthogonality relation to write the specified permutation character (cf. Example 3, Section 18.3) as a sum of irreducible characters:
  - (a) the permutation character of the subgroup  $A_3$  of  $S_3$
  - (b) the permutation character of the subgroup  $\langle (1\ 2\ 3\ 4) \rangle$  of  $S_4$
  - (c) the permutation character of the subgroup  $V_4$  of  $S_4$
  - (d) the permutation character of the subgroup  $\langle (1\ 2\ 3), (1\ 2), (4\ 5) \rangle$  of  $S_5$  (this subgroup is the normalizer of a Sylow 3-subgroup of  $S_5$ ).
5. Assume that for any character  $\psi$  of a group,  $\psi^2$  is also a character (where  $\psi^2(g) = (\psi(g))^2$ ) — this is a special case of Proposition 17 in Section 18.3. Using the character tables in this section, for each of parts (a) to (e) write out the values of the square,  $\chi^2$ , of the specified character  $\chi$  and use the first orthogonality relation to write  $\chi^2$  as a sum of irreducible characters:
  - (a)  $\chi = \chi_3$ , the degree 2 character in the table of  $S_3$
  - (b)  $\chi = \chi_5$ , the degree 2 character in the table of  $Q_8$
  - (c)  $\chi = \chi_5$ , the last character in the table of  $S_4$
  - (d)  $\chi = \chi_4$ , the second degree 4 character in the table of  $S_5$
  - (e)  $\chi = \chi_7$ , the last character in the table of  $S_5$ .
6. Calculate the character table of  $A_5$ .
7. Show that  $S_6$  has an irreducible character of degree 5.
8. Calculate the character table of  $D_{10}$ . (This table contains nonreal entries.)
9. Calculate the character table of  $D_{12}$ .
10. Calculate the character table of  $S_3 \times S_3$ .
11. Calculate the character table of  $Z_3 \times S_3$ .
12. Calculate the character table of  $Z_2 \times S_4$ .
13. Calculate the character table of  $S_3 \times S_4$ .
14. Let  $n$  be an integer with  $n \geq 3$ . Show that every irreducible character of  $D_{2n}$  has degree 1 or 2 and find the number of irreducible characters of each degree. [The conjugacy classes of  $D_{2n}$  were found in Exercises 31 and 32 of Section 4.3 and its commutator subgroup was computed in Section 5.4.]
15. Prove that the character table is an invertible matrix. [Use the orthogonality relations.]
16. For each of  $A_5$  and  $D_{10}$  describe which irreducible characters are algebraically conjugate (cf. the exercises in Section 18.3).

17. Let  $p$  be any prime and let  $P$  be a non-abelian group of order  $p^3$  (up to isomorphism there are two choices for  $P$ ; for odd  $p$  these were constructed when the groups of order  $p^3$  were classified in Section 5.5). This exercise determines the character table of  $P$  and shows that both isomorphism types have the same character table (the argument includes the  $p = 2$  case worked out in this section).
- Prove that  $P$  has  $p^2$  characters of degree 1.
  - Prove that  $P$  has  $p - 1$  irreducible characters of degree  $p$  and that these together with the  $p^2$  degree 1 characters are all the irreducible characters of  $P$ . [Use Theorem 10(3) and Theorem 12 in Section 18.2.]
  - Deduce that (regardless of the isomorphism type) the group  $P$  has  $p^2 + p - 1$  conjugacy classes,  $p$  of which are of size 1 (i.e., are central classes) and  $p^2 - 1$  of which each have size  $p$ . Deduce also that the classes of size  $p$  are precisely the nonidentity cosets of the center of  $P$  (i.e., if  $x \in P - Z(P)$  then the conjugacy class of  $x$  is the set of  $p$  elements in the coset  $xZ(P)$ ).
  - Prove that if  $\chi$  is an irreducible character of degree  $p$  then the representation affording  $\chi$  is faithful.
  - Fix a generator,  $z$ , of the center of  $P$  and let  $\epsilon$  be a fixed primitive  $p^{\text{th}}$  root of 1 in  $\mathbb{C}$ . Prove that if  $\chi$  is an irreducible character of degree  $p$  then  $\chi(z) = p\epsilon^i$  for some  $i \in \{1, 2, \dots, p - 1\}$ . Prove further that  $\chi(x) = 0$  for all  $x \in P - Z(P)$ . (Note then that the degree  $p$  characters are all algebraically conjugate.) [Use the same reasoning as in the construction of the character table of  $Q_8$ .]
  - Prove that for each  $i \in \{1, 2, \dots, p - 1\}$  there is a unique irreducible character  $\chi_i$  of degree  $p$  such that  $\chi_i(z) = p\epsilon^i$ . Deduce that the character table of  $P$  is uniquely determined, and describe it. [Recall from Section 6.1 that regardless of the isomorphism type,  $P' = Z(P)$  and  $P/P' \cong Z_p \times Z_p$ . From this one can write out the degree 1 characters. Part (e) describes the degree  $p$  characters.]

## 19.2 THEOREMS OF BURNSIDE AND HALL

In this section we give a “theoretical” application of character theory: Burnside’s  $p^aq^b$  Theorem. We also prove Philip Hall’s characterization of finite solvable groups, which is a group-theoretic proof relying on Burnside’s Theorem as the first step in its induction.

### Burnside’s Theorem

The following result was proved by Burnside in 1904. Although purely group-theoretic proofs of it were discovered recently (see Theorem 2.8 in *Finite Groups III* by B. Huppert and N. Blackburn, Springer-Verlag, 1982) the original proof by Burnside presented here is very accessible, elegant, and quite brief (given our present knowledge of representation theory).

**Theorem 1.** (Burnside) For  $p$  and  $q$  primes, every group of order  $p^aq^b$  is solvable.

Before undertaking the proof of Burnside’s Theorem itself we establish some results of a general nature. An easy consequence of these preliminary propositions is that the degrees of the irreducible characters of any finite group divide its order. The particular results that lead directly to the proof of Burnside’s Theorem appear in Lemmas 6 and 7.

It follows quite easily that a counterexample to Burnside's Theorem of minimal order is a non-abelian simple group, and it is these two character-theoretic lemmas that give the contradiction by proving the existence of a normal subgroup.

We first recall from Section 15.3 the definition of algebraic integers.

**Definition.** An element  $\alpha \in \mathbb{C}$  is called an *algebraic integer* if it is a root of a monic polynomial with coefficients from  $\mathbb{Z}$ .

The basic results needed for the proof of Burnside's Theorem are:

**Proposition 2.** Let  $\alpha \in \mathbb{C}$ .

- (1) The following are equivalent:
  - (i)  $\alpha$  is an algebraic integer,
  - (ii)  $\alpha$  is algebraic over  $\mathbb{Q}$  and the minimal polynomial of  $\alpha$  over  $\mathbb{Q}$  has integer coefficients, and
  - (iii)  $\mathbb{Z}[\alpha]$  is a finitely generated  $\mathbb{Z}$ -module (where  $\mathbb{Z}[\alpha]$  is the subring of  $\mathbb{C}$  generated by  $\mathbb{Z}$  and  $\alpha$ , i.e., is the ring of all  $\mathbb{Z}$ -linear combinations of nonnegative powers of  $\alpha$ ).
- (2) The algebraic integers in  $\mathbb{C}$  form a ring and the algebraic integers in  $\mathbb{Q}$  are the elements of  $\mathbb{Z}$ .

*Proof:* These are established in Section 15.3. (The portion of Section 15.3 consisting of integral extensions and properties of algebraic integers may be read independently from the rest of Chapter 15.)

**Corollary 3.** For every character  $\psi$  of the finite group  $G$ ,  $\psi(x)$  is an algebraic integer for all  $x \in G$ .

*Proof:* By Proposition 14 in Section 18.3,  $\psi(x)$  is a sum of roots of 1. Each root of 1 is an algebraic integer, so the result follows immediately from Proposition 2(2).

We shall also need some preliminary character-theoretic lemmas before beginning the main proof. Adopt the following notation for the arbitrary finite group  $G$ :  $\chi_1, \dots, \chi_r$  are the distinct irreducible (complex) characters of  $G$ ,  $\mathcal{K}_1, \dots, \mathcal{K}_r$  are the conjugacy classes of  $G$  and  $\varphi_i$  is an irreducible matrix representation whose character is  $\chi_i$  for each  $i$ .

**Proposition 4.** Define the complex valued function  $\omega_i$  on  $\{\mathcal{K}_1, \dots, \mathcal{K}_r\}$  for each  $i$  by

$$\omega_i(\mathcal{K}_j) = \frac{|\mathcal{K}_j| \chi_i(g)}{\chi_i(1)}$$

where  $g$  is any element of  $\mathcal{K}_j$ . Then  $\omega_i(\mathcal{K}_j)$  is an algebraic integer for all  $i$  and  $j$ .

*Proof:* We first prove that if  $I$  is the identity matrix, then

$$\sum_{g \in \mathcal{K}_j} \varphi_i(g) = \omega_i(\mathcal{K}_j)I. \quad (19.1)$$

To see this let  $X$  be the left hand side of (1). As we saw in Section 18.2, each  $x \in G$  acting by conjugation permutes the elements of  $\mathcal{K}_j$  and so  $X$  commutes with  $\varphi_i(g)$  for all  $g$ . By Schur's Lemma (Exercise 18 in Section 18.1)  $X$  is a scalar matrix:

$$X = \alpha I \quad \text{for some } \alpha \in \mathbb{C}.$$

It remains to show that  $\alpha = \omega_i(\mathcal{K}_j)$ . But

$$\operatorname{tr} X = \sum_{g \in \mathcal{K}_j} \operatorname{tr} \varphi_i(g) = \sum_{g \in \mathcal{K}_j} \chi_i(g) = |\mathcal{K}_j| \chi_i(g).$$

Thus  $\alpha \chi_i(1) = \operatorname{tr} X = |\mathcal{K}_j| \chi_i(g)$ , as needed to establish (1).

Now let  $g$  be a fixed element of  $\mathcal{K}_s$  and define  $a_{ijs}$  to be the number of ordered pairs  $g_i, g_j$  with  $g_i \in \mathcal{K}_i$ ,  $g_j \in \mathcal{K}_j$  and  $g_i g_j = g$ . Notice that  $a_{ijs}$  is an integer. It is independent of the choice of  $g$  in  $\mathcal{K}_s$  because if  $x^{-1}gx$  is a conjugate of  $g$ , every ordered pair  $g_i, g_j$  whose product is  $g$  gives rise to an ordered pair  $x^{-1}g_i x, x^{-1}g_j x$  whose product is  $x^{-1}gx$  (and vice versa).

Next we prove that for all  $i, j, t \in \{1, \dots, r\}$

$$\omega_t(\mathcal{K}_i) \omega_t(\mathcal{K}_j) = \sum_{s=1}^r a_{ijs} \omega_t(\mathcal{K}_s). \quad (19.2)$$

To see this note that by (1), the left hand side of (2) is the diagonal entry of the scalar matrix on the left of the following equation:

$$\begin{aligned} \left( \sum_{g \in \mathcal{K}_i} \varphi_t(g) \right) \left( \sum_{g \in \mathcal{K}_j} \varphi_t(g) \right) &= \sum_{g_i \in \mathcal{K}_i} \sum_{g_j \in \mathcal{K}_j} \varphi_t(g_i g_j) \\ &= \sum_{s=1}^r \sum_{g \in \mathcal{K}_s} a_{ijs} \varphi_t(g) \\ &= \sum_{s=1}^r a_{ijs} \sum_{g \in \mathcal{K}_s} \varphi_t(g) \quad (\text{since } a_{ijs} \text{ is independent of } g \in \mathcal{K}_s) \\ &= \sum_{s=1}^r a_{ijs} \omega_t(\mathcal{K}_s) I \quad (\text{by (1)}). \end{aligned}$$

Comparing entries of these scalar matrices gives (2).

Now (2) implies that the subring of  $\mathbb{C}$  generated by  $\mathbb{Z}$  and  $\omega_t(\mathcal{K}_1), \dots, \omega_t(\mathcal{K}_r)$  is a finitely generated  $\mathbb{Z}$ -module for each  $t \in \{1, \dots, r\}$  (it is generated as a  $\mathbb{Z}$ -module by  $1, \omega_t(\mathcal{K}_1), \dots, \omega_t(\mathcal{K}_r)$ ). Since  $\mathbb{Z}$  is a Principal Ideal Domain the submodule  $\mathbb{Z}[\omega_t(\mathcal{K}_i)]$  is also a finitely generated  $\mathbb{Z}$ -module, hence  $\omega_t(\mathcal{K}_i)$  is an algebraic integer by Proposition 2. This completes the proof.

**Corollary 5.** The degree of each complex irreducible representation of a finite group  $G$  divides the order of  $G$ , i.e.,  $\chi_i(1) \mid |G|$  for  $i = 1, 2, \dots, r$ .

*Proof:* Under the notation of Proposition 4 and with  $g_j \in \mathcal{K}_j$  we have

$$\begin{aligned}\frac{|G|}{\chi_i(1)} &= \frac{|G|}{\chi_i(1)}(\chi_i, \chi_i) \\ &= \sum_{j=1}^r \frac{|\mathcal{K}_j| \chi_i(g_j) \overline{\chi_i(g_j)}}{\chi_i(1)} \\ &= \sum_{j=1}^r \omega_i(\mathcal{K}_j) \overline{\chi_i(g_j)}.\end{aligned}$$

The right hand side is an algebraic integer and the left hand side is rational, hence is an integer. This proves the corollary.

The next two lemmas lead directly to Burnside's Theorem.

**Lemma 6.** If  $G$  is any group that has a conjugacy class  $\mathcal{K}$  and an irreducible matrix representation  $\varphi$  with character  $\chi$  such that  $(|\mathcal{K}|, \chi(1)) = 1$ , then for  $g \in \mathcal{K}$  either  $\chi(g) = 0$  or  $\varphi(g)$  is a scalar matrix.

*Proof:* By hypothesis there exist  $s, t \in \mathbb{Z}$  such that  $s|\mathcal{K}| + t\chi(1) = 1$ . Thus

$$s|\mathcal{K}|\chi(g) + t\chi(1)\chi(g) = \chi(g).$$

Divide both sides of this by  $\chi(1)$  and note that by Corollary 3 and Proposition 4 both  $\chi(g)$  and  $\frac{|\mathcal{K}|\chi(g)}{\chi(1)}$  are algebraic integers, hence so is  $\frac{\chi(g)}{\chi(1)}$ . Let  $a_1 = \frac{\chi(g)}{\chi(1)}$  and let  $a_1, a_2, \dots, a_n$  be all its algebraic conjugates over  $\mathbb{Q}$  (i.e., the roots of the minimal polynomial of  $a_1$  over  $\mathbb{Q}$ ). Since  $a_1$  is a sum of  $\chi(1)$  roots of 1 divided by the integer  $\chi(1)$ , each  $a_i$  is also a sum of  $\chi(1)$  roots of 1 divided by  $\chi(1)$ . Thus  $a_i$  has complex absolute value  $\leq 1$  for all  $i$ . Now  $b = \prod_{i=1}^n a_i \in \mathbb{Q}$  and  $b$  is an algebraic integer ( $\pm b$  is the constant term of the irreducible polynomial of  $a_1$ ), hence  $b \in \mathbb{Z}$ . But

$$|b| = \prod_{i=1}^n |a_i| \leq 1,$$

so  $b = 0, \pm 1$ . Since all  $a_i$ 's are conjugate,  $b = 0 \Leftrightarrow a_1 = 0 \Leftrightarrow \chi(g) = 0$ . Also,  $b = \pm 1 \Leftrightarrow |a_i| = 1$  for all  $i$ . Thus either  $\chi(g) = 0$  or  $|\chi(g)| = \chi(1)$ . In the former situation the lemma is established, so assume  $|\chi(g)| = \chi(1)$ .

Let  $\varphi_1$  be a matrix representation equivalent to  $\varphi$  in which  $\varphi_1(g)$  is a diagonal matrix:

$$\varphi_1(g) = \begin{pmatrix} \epsilon_1 & & & \\ & \epsilon_2 & & \\ & & \ddots & \\ & & & \epsilon_n \end{pmatrix}.$$

Thus  $\chi(g) = \epsilon_1 + \cdots + \epsilon_n$ . By the triangle inequality if  $\epsilon_i \neq \epsilon_j$  for any  $i, j$ , then  $|\epsilon_1 + \cdots + \epsilon_n| < n = \chi(1)$ . Since this is not the case we must have  $\varphi_1(g) = \epsilon I$  (where  $\epsilon = \epsilon_i$  for all  $i$ ). Since scalar matrices are similar only to themselves,  $\varphi(g) = \epsilon I$  as well. This completes the proof.

**Lemma 7.** If  $|\mathcal{K}|$  is a power of a prime for some nonidentity conjugacy class  $\mathcal{K}$  of  $G$ , then  $G$  is not a non-abelian simple group.

*Proof:* Suppose to the contrary that  $G$  is a non-abelian simple group and let  $|\mathcal{K}| = p^c$ . Let  $g \in \mathcal{K}$ . If  $c = 0$  then  $g \in Z(G)$ , contrary to a non-abelian simple group having a trivial center. As above, let  $\chi_1, \dots, \chi_r$  be all the irreducible characters of  $G$  with  $\chi_1$  the principal character and let  $\rho$  be the regular character of  $G$ . By decomposing  $\rho$  into irreducibles we obtain

$$0 = \rho(g) = 1 + \sum_{i=2}^r \chi_i(1)\chi_i(g). \quad (19.3)$$

If  $p \mid \chi_j(1)$  for every  $j > 1$  with  $\chi_j(g) \neq 0$ , then write  $\chi_j(1) = pd_j$ . In this case (3) becomes

$$0 = 1 + p \sum_j d_j \chi_j(g).$$

Thus  $\sum_j d_j \chi_j(g) = -1/p$  is an algebraic integer, a contradiction. This proves there is some  $j$  such that  $p$  does not divide  $\chi_j(1)$  and  $\chi_j(g) \neq 0$ . If  $\varphi$  is a representation whose character is  $\chi_j$ , then  $\varphi$  is faithful (because  $G$  is assumed to be simple) and, by Lemma 6,  $\varphi(g)$  is a scalar matrix. Since  $\varphi(g)$  commutes with all matrices,  $\varphi(g) \in Z(\varphi(G))$ . This forces  $g \in Z(G)$ , contrary to  $G$  being a non-abelian simple group. The proof of the lemma is complete.

We now prove Burnside's Theorem. Let  $G$  be a group of order  $p^a q^b$  for some primes  $p$  and  $q$ . If  $p = q$  or if either exponent is 0 then  $G$  is nilpotent hence solvable. Thus we may assume this is not the case. Proceeding by induction let  $G$  be a counterexample of minimal order. If  $G$  has a proper, nontrivial normal subgroup  $N$ , then by induction both  $N$  and  $G/N$  are solvable, hence so is  $G$  (cf. Section 3.4 or Proposition 6.10). Thus we may assume  $G$  is a non-abelian simple group. Let  $P \in Syl_p(G)$ . By Theorem 8 of Chapter 4 there exists  $g \in Z(P)$  with  $g \neq 1$ . Since  $P \leq C_G(g)$ , the order of the conjugacy class of  $g$  (which equals  $|G : C_G(g)|$ ) is prime to  $p$ , i.e., is a power of  $q$ . This violates Lemma 7 and so completes the proof of Burnside's Theorem.

## Philip Hall's Theorem

Recall that a subgroup of a finite group is called a *Hall subgroup* if its order and index are relatively prime. For any subgroup  $H$  of a group  $G$  a subgroup  $K$  such that  $G = HK$  and  $H \cap K = 1$  is called a *complement* to  $H$  in  $G$ .

**Theorem 8.** (P. Hall) Let  $G$  be a group of order  $p_1^{\alpha_1} p_2^{\alpha_2} \cdots p_t^{\alpha_t}$  where  $p_1, \dots, p_t$  are distinct primes. If for each  $i \in \{1, \dots, t\}$  there exists a subgroup  $H_i$  of  $G$  with  $|G : H_i| = p_i^{\alpha_i}$ , then  $G$  is solvable.

Hall's Theorem can also be phrased: if for each  $i \in \{1, \dots, t\}$  a Sylow  $p_i$ -subgroup of  $G$  has a complement, then  $G$  is solvable. The converse to Hall's Theorem is also true — this was Exercise 33 in Section 6.1.

We shall first need some elementary lemmas.

**Lemma 9.** If  $G$  is solvable of order  $> 1$ , then there exists  $P \trianglelefteq G$  with  $P$  a nontrivial  $p$ -group for some prime  $p$ .

*Proof:* This is a special case of the exercise on minimal normal subgroups of solvable groups at the end of Section 6.1. One can see this easily by letting  $P$  be a nontrivial Sylow subgroup of the last nontrivial term,  $G^{(n-1)}$ , in the derived series of  $G$  (where  $G$  has solvable length  $n$ ). In this case  $G^{(n-1)}$  is abelian so  $P$  is a characteristic subgroup of  $G^{(n-1)}$ , hence is normal in  $G$ .

**Lemma 10.** Let  $G$  be a group of order  $p_1^{\alpha_1} p_2^{\alpha_2} \cdots p_t^{\alpha_t}$  where  $p_1, \dots, p_t$  are distinct primes. Suppose there are subgroups  $H$  and  $K$  of  $G$  such that for each  $i \in \{1, \dots, t\}$ , either  $p_i^{\alpha_i}$  divides  $|H|$  or  $p_i^{\alpha_i}$  divides  $|K|$ . Then  $G = HK$  and  $|H \cap K| = (|H|, |K|)$ .

*Proof:* Fix some  $i \in \{1, \dots, t\}$  and suppose first that  $p_i^{\alpha_i}$  divides the order of  $H$ . Since  $HK$  is a disjoint union of right cosets of  $H$  and each of these right cosets has order equal to  $|H|$ , it follows that  $p_i^{\alpha_i}$  divides  $|HK|$ . Similarly, if  $p_i^{\alpha_i}$  divides  $|K|$ , since  $HK$  is a disjoint union of left cosets of  $K$ , again  $p_i^{\alpha_i}$  divides  $|HK|$ . Thus  $|G| \mid |HK|$  and so  $G = HK$ . Since

$$|HK| = \frac{|H||K|}{|H \cap K|},$$

it follows that  $|H \cap K| = (|H|, |K|)$ .

We now begin the proof of Hall's Theorem, proceeding by induction on  $|G|$ . Note that if  $t = 1$  the hypotheses are trivially satisfied for any group ( $H_1 = 1$ ) and if  $t = 2$  the hypotheses are again satisfied for any group by Sylow's Theorem ( $H_1$  is a Sylow  $p_2$ -subgroup of  $G$  and  $H_2$  is a Sylow  $p_1$ -subgroup of  $G$ ). If  $t = 1$ ,  $G$  is nilpotent, hence solvable and if  $t = 2$ ,  $G$  is solvable by Burnside's Theorem. Assume therefore that  $t \geq 3$ .

Fix  $i$  and note that by the preceding lemma, for all  $j \in \{1, \dots, t\} - \{i\}$ ,

$$|H_i : H_i \cap H_j| = p_j^{\alpha_j}.$$

Thus every Sylow  $p_j$ -subgroup of  $H_i$  has a complement in  $H_i$ :  $H_j \cap H_i$ . By induction  $H_i$  is solvable.

By Lemma 9 we may choose  $P \trianglelefteq H_1$  with  $|P| = p_i^a > 1$  for some  $i > 1$ . Since  $t \geq 3$  there exists an index  $j \in \{1, \dots, t\} - \{1, i\}$ . By Lemma 10

$$|H_1 \cap H_j| = p_2^{\alpha_2} \cdots p_{j-1}^{\alpha_{j-1}} p_{j+1}^{\alpha_{j+1}} \cdots p_t^{\alpha_t}.$$

Thus  $H_1 \cap H_j$  contains a Sylow  $p_i$ -subgroup of  $H_1$ . Since  $P$  is a normal  $p_i$ -subgroup of  $H_1$ ,  $P$  is contained in every Sylow  $p_i$ -subgroup of  $H_1$  and so  $P \leq H_1 \cap H_j$ . By Lemma 10,  $G = H_1 H_j$  so each  $g \in G$  may be written  $g = h_1 h_j$  for some  $h_1 \in H_1$  and  $h_j \in H_j$ . Then

$$g H_j g^{-1} = (h_1 h_j) H_j (h_1 h_j)^{-1} = h_1 H_j h_1^{-1}$$

and so

$$\bigcap_{g \in G} g H_j g^{-1} = \bigcap_{h_1 \in H_1} h_1 H_j h_1^{-1}.$$

Now  $P \leq H_j$  and  $h_1 Ph_1^{-1} = P$  for all  $h_1 \in H_1$ . Thus

$$1 \neq P \leq \bigcap_{h_1 \in H_1} h_1 H_j h_1^{-1}.$$

Thus  $N = \bigcap_{g \in G} g H_j g^{-1}$  is a nontrivial, proper normal subgroup of  $G$ . It follows that both  $N$  and  $G/N$  satisfy the hypotheses of the theorem (cf. the exercises in Section 3.3). Both  $N$  and  $G/N$  are solvable by induction, so  $G$  is solvable. This completes the proof of Hall's Theorem.

## EXERCISES

1. Show that every character of the symmetric group  $S_n$  is integer valued, for all  $n$  (i.e.,  $\psi(g) \in \mathbb{Z}$  for all  $g \in S_n$  and all characters  $\psi$  of  $S_n$ ). [See Exercise 22 in Section 18.3.]
2. Let  $G$  be a finite group with the property that every maximal subgroup has either prime or prime squared index. Prove that  $G$  is solvable. (The simple group  $GL_3(\mathbb{F}_2)$  has the property that every maximal subgroup has index either 7 or 8, i.e., either prime or prime cubed index — cf. Section 6.2.). [Let  $p$  be the largest prime dividing  $|G|$  and let  $P$  be a Sylow  $p$ -subgroup of  $G$ . If  $P \trianglelefteq G$ , apply induction to  $G/P$ . Otherwise let  $M$  be a maximal subgroup containing  $N_G(P)$ . Use Exercise 51 in Section 4.5 to show that  $p = 3$  and deduce that  $|G| = 2^a 3^b$ .]
3. Assume  $G$  is a finite group that possesses an abelian subgroup  $H$  whose index is a power of a prime. Prove that  $G$  is solvable.
4. Repeat the preceding exercise with the word “abelian” replaced by “nilpotent.”
5. Use the ideas in the proof of Philip Hall's Theorem to prove Burnside's  $p^a q^b$  Theorem in the special case when all Sylow subgroups are abelian (without use of character theory.)

## 19.3 INTRODUCTION TO THE THEORY OF INDUCED CHARACTERS

Let  $G$  be a finite group, let  $H$  be a subgroup of  $G$  and let  $\varphi$  be a representation of the subgroup  $H$  over an arbitrary field  $F$ . In this section we show how to obtain a representation of  $G$ , called the induced representation, from the representation  $\varphi$  of its subgroup. We also determine a formula for the character of this induced representation, the induced character, in terms of the character of  $\varphi$  and we illustrate this formula by computing some induced characters in specific groups. Finally, we apply the theory of induced characters to prove that there are no simple groups of order  $3^3 \cdot 7 \cdot 13 \cdot 409$ , a group order which was discussed at the end of Section 6.2 in the context of the existence problem for simple groups. The theory of induced representations and induced characters marks the beginning of more advanced representation theory. This section is intended as an introduction rather than as a comprehensive treatment, and the results we have included were chosen to serve this purpose.

First observe that it may not be possible to extend a representation  $\varphi$  of the subgroup  $H$  to a representation  $\Phi$  of  $G$  in such a way that  $\Phi|_H = \varphi$ . For example,  $A_3 \leq S_3$  and  $A_3$  has a faithful representation of degree 1 (cf. Section 1). Since every degree 1 representation of  $S_3$  contains  $A_3 = S'_3$  in its kernel, this representation of  $A_3$  cannot be extended to a representation of  $S_3$ . For another example of a representation of a

subgroup which cannot be extended to the whole group take  $G$  to be any simple group and let  $\varphi$  be any representation of  $H$  with the property that  $\ker \varphi$  is a proper, nontrivial normal subgroup of  $H$ . If  $\varphi$  extended to a representation  $\Phi$  of  $G$  then the kernel of  $\Phi$  would be a proper, nontrivial subgroup of  $G$ , contrary to  $G$  being a simple group. We shall see that the method of induced characters produces a representation  $\Phi$  of  $G$  from a given representation  $\varphi$  of its subgroup  $H$  but that  $\Phi|_H \neq \varphi$  in general (indeed, unless  $H = G$  the degree of  $\Phi$  will be greater than the degree of  $\varphi$ ).

We saw in Example 5 following Corollary 9 in Section 10.4 that because  $FH$  is a subring of  $FG$ , the ring  $FG$  is an  $(FG, FH)$ -bimodule; and so for any left  $FH$ -module  $V$ , the abelian group  $FG \otimes_{FH} V$  is a left  $FG$ -module (called the extension of scalars from  $FH$  to  $FG$  for  $V$ ). In the representation theory of finite groups this extension is given a special name.

**Definition.** Let  $H$  be a subgroup of the finite group  $G$  and let  $V$  be an  $FH$ -module affording the representation  $\varphi$  of  $H$ . The  $FG$ -module  $FG \otimes_{FH} V$  is called the *induced module* of  $V$  and the representation of  $G$  it affords is called the *induced representation* of  $\varphi$ . If  $\psi$  is the character of  $\varphi$  then the character of the induced representation is called the *induced character* and is denoted by  $\text{Ind}_H^G(\psi)$ .

**Theorem 11.** Let  $H$  be a subgroup of the finite group  $G$  and let  $g_1, \dots, g_m$  be representatives for the distinct left cosets of  $H$  in  $G$ . Let  $V$  be an  $FH$ -module affording the matrix representation  $\varphi$  of  $H$  of degree  $n$ . The  $FG$ -module  $W = FG \otimes_{FH} V$  has dimension  $nm$  over  $F$  and there is a basis of  $W$  such that  $W$  affords the matrix representation  $\Phi$  defined for each  $g \in G$  by

$$\Phi(g) = \begin{pmatrix} \varphi(g_1^{-1}gg_1) & \cdots & \varphi(g_1^{-1}gg_m) \\ \vdots & \ddots & \vdots \\ \varphi(g_m^{-1}gg_1) & \cdots & \varphi(g_m^{-1}gg_m) \end{pmatrix}$$

where each  $\varphi(g_i^{-1}gg_j)$  is an  $n \times n$  block appearing in the  $i, j$  block position of  $\Phi(g)$ , and where  $\varphi(g_i^{-1}gg_j)$  is defined to be the zero block whenever  $g_i^{-1}gg_j \notin H$ .

*Proof:* First note that  $FG$  is a free right  $FH$ -module:

$$FG = g_1FH \oplus g_2FH \oplus \cdots \oplus g_mFH.$$

Since tensor products commute with direct sums (Theorem 17, Section 10.4), as abelian groups we have

$$W = FG \otimes_{FH} V \cong (g_1 \otimes V) \oplus (g_2 \otimes V) \oplus \cdots \oplus (g_m \otimes V).$$

Since  $F$  is in the center of  $FG$  it follows that this is an  $F$ -vector space isomorphism as well. Thus if  $v_1, v_2, \dots, v_n$  is a basis of  $V$  affording the matrix representation  $\varphi$ , then  $\{g_i \otimes v_j \mid 1 \leq i \leq m, 1 \leq j \leq n\}$  is a basis of  $W$ . This shows the dimension of  $W$  is  $mn$ . Order the basis into  $m$  sets, each of size  $n$  as

$$g_1 \otimes v_1, g_1 \otimes v_2, \dots, g_1 \otimes v_n, g_2 \otimes v_1, \dots, g_2 \otimes v_n, \dots, g_m \otimes v_n.$$

We compute the matrix representation  $\Phi(g)$  of each  $g$  acting on  $W$  with respect to this basis. Fix  $j$  and  $g$ , and let  $gg_j = g_i h$  for some index  $i$  and some  $h \in H$ . Then for every  $k$

$$\begin{aligned} g(g_j \otimes v_k) &= (gg_j) \otimes v_k = g_i \otimes hv_k \\ &= \sum_{t=1}^n a_{tk}(h)(g_i \otimes v_t) \end{aligned}$$

where  $a_{tk}$  is the  $t, k$  coefficient of the matrix of  $h$  acting on  $V$  with respect to the basis  $\{v_1, \dots, v_n\}$ . In other words, the action of  $g$  on  $W$  maps the  $j^{\text{th}}$  block of  $n$  basis vectors of  $W$  to the  $i^{\text{th}}$  block of basis vectors, and then has the matrix  $\varphi(h)$  on that block. Since  $h = g_i^{-1}gg_j$ , this describes the block matrix  $\Phi(g)$  of the theorem, as needed.

**Corollary 12.** In the notation of Theorem 11

- (1) if  $\psi$  is the character afforded by  $V$  then the induced character is given by

$$\text{Ind}_H^G(\psi)(g) = \sum_{i=1}^m \psi(g_i^{-1}gg_i)$$

where  $\psi(g_i^{-1}gg_i)$  is defined to be 0 if  $g_i^{-1}gg_i \notin H$ , and

- (2)  $\text{Ind}_H^G(\psi)(g) = 0$  if  $g$  is not conjugate in  $G$  to some element of  $H$ . In particular, if  $H$  is a normal subgroup of  $G$  then  $\text{Ind}_H^G(\psi)$  is zero on all elements of  $G - H$ .

*Remark:* Since the character  $\psi$  of  $H$  is constant on the conjugacy classes of  $H$  we have  $\psi(g) = \psi(h^{-1}gh)$  for all  $h \in H$ . As  $h$  runs over all elements of  $H$ ,  $xh$  runs over all elements of the coset  $xH$ . Thus the formula for the induced character may also be written

$$\text{Ind}_H^G(\psi)(g) = \frac{1}{|H|} \sum_{x \in G} \psi(x^{-1}gx)$$

where the elements  $x$  in each fixed coset give the same character value  $|H|$  times (which accounts for the factor of  $1/|H|$ ), and again  $\psi(x^{-1}gx) = 0$  if  $x^{-1}gx \notin H$ .

*Proof:* From the matrix of  $g$  computed above, the blocks  $\varphi(g_i^{-1}gg_i)$  down the diagonal of  $\Phi(g)$  are zero except when  $g_i^{-1}gg_i \in H$ . Thus the trace of the block matrix  $\Phi(g)$  is the sum of the traces of the matrices  $\varphi(g_i^{-1}gg_i)$  for which  $g_i^{-1}gg_i \in H$ . Since the trace of  $\varphi(g_i^{-1}gg_i)$  is  $\psi(g_i^{-1}gg_i)$ , part (1) holds.

If  $g_i^{-1}gg_i \notin H$  for all coset representatives  $g_i$  then each term in the sum for  $\text{Ind}_H^G(\psi)(g)$  is zero. In particular, if  $g$  is not in the normal subgroup  $H$  then neither is any conjugate of  $g$ , so  $\text{Ind}_H^G(\psi)$  is zero on  $g$ .

## Examples

- (1) Let  $G = D_{12} = \langle r, s \mid r^6 = s^2 = 1, rs = sr^{-1} \rangle$  be the dihedral group of order 12 and let  $H = \{1, s, r^3, sr^3\}$ , so that  $H$  is isomorphic to the Klein 4-group and  $|G : H| = 3$ . Following the notation of Theorem 11 we exhibit the matrices for  $r$  and  $s$  of the induced

representation of a specific representation  $\varphi$  of  $H$ . Let the representation of  $H$  on a 2-dimensional vector space over  $\mathbb{Q}$  with respect to some basis  $v_1, v_2$  be given by

$$\varphi(s) = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix} = A, \quad \varphi(r^3) = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} = B, \quad \varphi(sr^3) = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix} = C,$$

so  $n = 2, m = 3$  and the induced representation  $\Phi$  has degree  $nm = 6$ . Fix representatives  $g_1 = 1, g_2 = r$ , and  $g_3 = r^2$  for the left cosets of  $H$  in  $G$ , so that  $g_k = r^{k-1}$ . Then

$$g_i^{-1}rg_j = r^{-(i-1)+1+(j-1)} = r^{j-i+1}, \text{ and}$$

$$g_i^{-1}sg_j = sr^{(i-1)+(j-1)} = sr^{i+j-2}.$$

Thus the  $6 \times 6$  matrices for the induced representation are seen to be

$$\Phi(r) = \begin{pmatrix} 0 & 0 & B \\ I & 0 & 0 \\ 0 & I & 0 \end{pmatrix} \quad \Phi(s) = \begin{pmatrix} A & 0 & 0 \\ 0 & 0 & C \\ 0 & C & 0 \end{pmatrix}$$

where the  $2 \times 2$  matrices  $A, B$  and  $C$  are given above,  $I$  is the  $2 \times 2$  identity matrix and 0 denotes the  $2 \times 2$  zero matrix.

- (2) If  $H$  is any subgroup of  $G$  and  $\psi_1$  is the principal character of  $H$ , then  $\text{Ind}_H^G(\psi_1)(g)$  counts 1 for each coset representative  $g_i$  such that  $g_i^{-1}gg_i \in H$ . Since  $g_i^{-1}gg_i \in H$  if and only if  $g$  fixes the left coset  $g_iH$  under left multiplication,  $\text{Ind}_H^G(\psi_1)(g)$  is the number of points fixed by  $g$  in the permutation representation of  $g$  on the left cosets of  $H$ . Thus by Example 3 of Section 18.3 we see that: *if  $\psi_1$  is the principal character of  $H$  then  $\text{Ind}_H^G(\psi_1)$  is the permutation character on the left cosets of  $H$  in  $G$ .* In the special case when  $H = 1$ , this implies *if  $\chi_1$  is the principal character of the trivial subgroup  $H = 1$  then  $\text{Ind}_1^G(\chi_1)$  is the regular character of  $G$ .* This also shows that an induced character is not, in general, irreducible even if the character from which it is induced is irreducible.
- (3) Let  $G = S_3$  and let  $\psi$  be a nonprincipal linear character of  $A_3 = \langle x \rangle$ , so that  $\psi(x) = \zeta$ , for some primitive cube root of unity  $\zeta$  (the character tables of  $A_3 = Z_3$  and  $S_3$  appear in Section 1). Let  $\Psi = \text{Ind}_{A_3}^{S_3}(\psi)$ . Thus  $\Psi$  has degree  $1 \cdot |S_3 : A_3| = 2$  and, by the corollary,  $\Psi$  is zero on all transpositions. If  $y$  is any transposition then  $1, y$  is a set of left coset representatives of  $A_3$  in  $S_3$  and  $y^{-1}xy = x^2$ . Thus  $\Psi(x) = \psi(x) + \psi(x^2)$  equals  $\zeta + \zeta^2 = -1$ . This shows that if  $\psi$  is either of the two nonprincipal irreducible characters of  $A_3$  then the induced character of  $\psi$  is the (unique) irreducible character of  $S_3$  of degree 2. In particular, different characters of a subgroup may induce the same character of the whole group.
- (4) Let  $G = D_8$  have its usual generators and relations and let  $H = \langle s \rangle$ . Let  $\psi$  be the nonprincipal irreducible character of  $H$  and let  $\Psi = \text{Ind}_H^G(\psi)$ . Pick left coset representatives  $1, r, r^2, r^3$  for  $H$ . By Theorem 11,  $\Psi(1) = 4$ . Since  $\psi(s) = -1$ , one computes directly that  $\Psi(s) = -2$ . By Corollary 12(2) we obtain  $\Psi(r) = \Psi(r^2) = \Psi(sr) = 0$ . In the notation of the character table of  $D_8$  in Section 1, by the orthogonality relations we obtain  $\Psi = \chi_2 + \chi_4 + \chi_5$  (which may be checked by inspection).

For the remainder of this section the field  $F$  is taken to be the complex numbers:  $F = \mathbb{C}$ .

Before concluding with an application of induced characters to simple groups we compute the characters of an important class of groups.

**Definition.** A finite group  $G$  is called a *Frobenius group* with *Frobenius kernel*  $Q$  if  $Q$  is a proper, nontrivial normal subgroup of  $G$  and  $C_G(x) \leq Q$  for all nonidentity elements  $x$  of  $Q$ .

In view of the application to simple groups mentioned at the beginning of this section we shall restrict attention to Frobenius groups  $G$  of order  $q^a p$ , where  $p$  and  $q$  are distinct primes, such that the Frobenius kernel  $Q$  is an elementary abelian  $q$ -group of order  $q^a$  and the cyclic group  $G/Q$  acts irreducibly by conjugation on  $Q$ . In other words, we shall assume  $Q$  is a direct product of cyclic groups of order  $q$  and the only normal subgroups of  $G$  that are contained in  $Q$  are 1 and  $Q$ , i.e.,  $Q$  is a minimal normal subgroup of  $G$ . For example,  $A_4$  is a Frobenius group of this type with Frobenius kernel  $V_4$ , its Sylow 2-subgroup. Also, if  $p$  and  $q$  are distinct primes with  $p < q$  and  $G$  is a non-abelian group of order  $pq$  (one always exists if  $p \mid q - 1$ ) then  $G$  is a Frobenius group whose Frobenius kernel is its Sylow  $q$ -subgroup (which is normal by Sylow's Theorem). We essentially determine the character table of these Frobenius groups. Analogous results on more general Frobenius groups appear in the exercises.

**Proposition 13.** Let  $G$  be a Frobenius group of order  $q^a p$ , where  $p$  and  $q$  are distinct primes, such that the Frobenius kernel  $Q$  is an elementary abelian  $q$ -group of order  $q^a$  and the cyclic group  $G/Q$  acts irreducibly by conjugation on  $Q$ . Then the following hold:

- (1)  $G = QP$  where  $P$  is a Sylow  $p$ -subgroup of  $G$ . Every nonidentity element of  $G$  has order  $p$  or  $q$ . Every element of order  $p$  is conjugate to an element of  $P$  and every element of order  $q$  belongs to  $Q$ . The nonidentity elements of  $P$  represent the  $p - 1$  distinct conjugacy classes of elements of order  $p$  and each of these classes has size  $q^a$ . There are  $(q^a - 1)/p$  distinct conjugacy classes of elements of order  $q$  and each of these classes has size  $p$ .
- (2)  $G' = Q$  so the number of degree 1 characters of  $G$  is  $p$  and every degree 1 character contains  $Q$  in its kernel.
- (3) If  $\psi$  is any nonprincipal irreducible character of  $Q$ , then  $\text{Ind}_Q^G(\psi)$  is an irreducible character of  $G$ . Moreover, every irreducible character of  $G$  of degree  $> 1$  is equal to  $\text{Ind}_Q^G(\psi)$  for some nonprincipal irreducible character  $\psi$  of  $Q$ . Every irreducible character of  $G$  has degree either 1 or  $p$  and the number of irreducible characters of degree  $p$  is  $(q^a - 1)/p$ .

*Proof:* Note that  $QP$  equals  $G$  by order consideration. By definition of a Frobenius group and because  $Q$  is abelian,  $C_G(h) = Q$  for every nonidentity element  $h$  of  $Q$ . If  $x$  were an element of order  $pq$ , then  $x^p$  would be an element of order  $q$ , hence would lie in the unique Sylow  $q$ -subgroup  $Q$  of  $G$ . But then  $x$  would commute with  $x^p$  and so  $x$  would belong to  $C_G(x^p) = Q$ , a contradiction. Thus  $G$  has no elements of order  $pq$ . By Sylow's Theorem every element of order  $p$  is conjugate to an element of  $P$  and every element of order  $q$  lies in  $Q$ . No two distinct elements of  $P$  are conjugate in  $G$  because if  $g^{-1}xg = y$  for some  $x, y \in P$  then  $\overline{g^{-1}xg} = \overline{y}$  in the abelian group  $\overline{G} = G/Q$  and so  $\overline{x} = \overline{y}$ . Then  $x = y$  because  $\overline{P} \cong P$ . Thus there are exactly  $p - 1$  conjugacy classes of elements of order  $p$  and these are represented by the nonidentity elements of  $P$ . If  $x$  is a nonidentity element of  $P$ , then  $C_G(x) = P$  and so the conjugacy class of

$x$  consists of  $|G : P| = q^a$  elements. Finally, if  $h$  is a nonidentity element of  $Q$ , then  $C_G(h) = Q$  and the conjugacy class of  $h$  is  $\{h, h^x, \dots, h^{x^{p-1}}\}$ , where  $P = \langle x \rangle$ . This proves all parts of (1).

Since  $G/Q$  is abelian,  $G' \leq Q$ . Since  $G$  is non-abelian and  $Q$  is, by hypothesis, a minimal normal subgroup of  $G$  we must have  $G' = Q$ . Part (2) now follows from Corollary 11 in Section 18.2.

Let  $\psi$  be a nonprincipal irreducible character of  $Q$  and let  $\Psi = \text{Ind}_Q^G(\psi)$ . We use the orthogonality relations to show that  $\Psi$  is irreducible. Let  $1, x, \dots, x^{p-1}$  be coset representatives for  $Q$  in  $G$ . By Corollary 12,  $\Psi$  is zero on  $G - Q$  so

$$\begin{aligned} \|\Psi\|^2 &= \frac{1}{|G|} \sum_{h \in Q} \Psi(h) \overline{\Psi(h)} \\ &= \frac{1}{|G|} \sum_{h \in Q} \sum_{i=0}^{p-1} \psi(x^i h x^{-i}) \overline{\psi(x^i h x^{-i})} \\ &= \frac{p}{|G|} \sum_{h \in Q} \psi(h) \overline{\psi(h)} \\ &= \frac{p|Q|}{|G|} = 1, \end{aligned}$$

where the second line follows from the definition of the induced character  $\Psi$ , the third line follows because each element of  $Q$  appears exactly  $p$  times in the sum in the second line, and the last line follows from the first orthogonality relation in  $Q$  because  $\psi$  is an irreducible character of  $Q$ . This proves  $\Psi$  is an irreducible character of  $G$ .

We prove that every irreducible character of  $G$  of degree  $> 1$  is the induced character of some nonprincipal degree 1 character of  $Q$  by counting the number of distinct irreducible characters of  $G$  obtained this way. By parts (1) and (2) the number of irreducible characters of  $G$  (= the number of conjugacy classes) is  $p + (q^a - 1)/p$  and the number of degree 1 characters is  $p$ . Thus the number of irreducible characters of  $G$  of degree  $> 1$  is  $(q^a - 1)/p$ . The group  $P$  acts on the set  $\mathcal{C}$  of nonprincipal irreducible characters of  $Q$  as follows: for each  $\psi \in \mathcal{C}$  and each  $x \in P$  let  $\psi^x$  be defined by

$$\psi^x(h) = \psi(xhx^{-1}) \quad \text{for all } h \in Q.$$

Since  $\psi$  is a nontrivial homomorphism from  $Q$  into  $\mathbb{C}^\times$  (recall that all irreducible characters of the abelian group  $Q$  have degree 1) it follows easily that  $\psi^x$  is also a homomorphism. Thus  $\psi^x \in \mathcal{C}$  and so  $P$  permutes the elements of  $\mathcal{C}$ . Now let  $x$  be a generator for the cyclic group  $P$ . Then  $1, x, \dots, x^{p-1}$  are representatives for the left cosets of  $Q$  in  $G$ . By Corollary 12 applied with this set of coset representatives we see that if  $\psi \in \mathcal{C}$  then the value of  $\text{Ind}_Q^G(\psi)$  on any element  $h$  of  $Q$  is given by the sum  $\psi(h) + \psi^x(h) + \dots + \psi^{x^{p-1}}(h)$ . Thus when the induced character  $\text{Ind}_Q^G(\psi)$  is restricted to  $Q$  it decomposes into irreducible characters of  $Q$  as

$$\text{Ind}_Q^G(\psi)|_Q = \psi + \psi^x + \dots + \psi^{x^{p-1}}.$$

If  $\psi_1$  and  $\psi_2$  are in different orbits of the action of  $P$  on  $\mathcal{C}$  then the induced characters  $\text{Ind}_Q^G(\psi_1)$  and  $\text{Ind}_Q^G(\psi_2)$  restrict to distinct characters of  $Q$  (they have no irreducible

constituents in common). Thus characters induced from elements of distinct orbits of  $P$  on  $\mathcal{C}$  are distinct irreducible characters of  $G$ . The abelian group  $Q$  has  $q^a - 1$  nonprincipal irreducible characters (i.e.,  $|\mathcal{C}| = q^a - 1$ ) and  $|P| = p$  so there are at least  $(q^a - 1)/p$  orbits of  $P$  on  $\mathcal{C}$  and hence at least this number of distinct irreducible characters of  $G$  of degree  $p$ . Since  $G$  has exactly  $(q^a - 1)/p$  irreducible characters of degree  $> 1$ , every irreducible character of  $G$  of degree  $> 1$  must have degree  $p$  and must be an induced character from some element of  $\mathcal{C}$ . The proof is complete.

For the final example we shall require two properties of induced characters. These properties are listed in the next proposition and the proofs are straightforward exercises which follow easily from the formula for induced characters or from the definition of induced modules together with properties of tensor products.

**Proposition 14.** Let  $G$  be a group, let  $H$  be a subgroup of  $G$  and let  $\psi$  and  $\psi'$  be characters of  $H$ .

(1) (*Induction of characters is additive*)  $\text{Ind}_H^G(\psi + \psi') = \text{Ind}_H^G(\psi) + \text{Ind}_H^G(\psi')$ .

(2) (*Induction of characters is transitive*) If  $H \leq K \leq G$  then

$$\text{Ind}_K^G(\text{Ind}_H^K(\psi)) = \text{Ind}_H^G(\psi).$$

It follows from part (1) of Proposition 14 that if  $\sum_{i=1}^s n_i \psi_i$  is any integral linear combination of characters of  $H$  with  $n_i \geq 0$  for all  $i$  then

$$\text{Ind}_H^G\left(\sum_{i=1}^s n_i \psi_i\right) = \sum_{i=1}^s n_i \text{Ind}_H^G(\psi_i). \quad (*)$$

A class function of  $H$  of the form  $\sum_{i=1}^s n_i \psi_i$ , where the coefficients are any integers (not necessarily nonnegative) is called a *generalized character* or *virtual character* of  $H$ . For a generalized character of  $H$  we define its induced generalized character of  $G$  by equation (\*), allowing now negative coefficients  $n_i$  as well. In this way the function  $\text{Ind}_H^G$  becomes a group homomorphism from the additive group of generalized characters of  $H$  to the additive group of generalized characters of  $G$  (which maps characters to characters). This implies that the formula for induced characters in Corollary 12 holds also if  $\psi$  is a generalized character of  $H$ .

### Application to Groups of Order $3^3 \cdot 7 \cdot 13 \cdot 409$

We now conclude with a proof of the following result:

*there are no simple groups of order  $3^3 \cdot 7 \cdot 13 \cdot 409$ .*

As mentioned at the beginning of this section, simple groups of this order were discussed at the end of Section 6.2 in the context of the existence problem for simple groups. It is possible to prove that there are no simple groups of this order by arguments involving a permutation representation of degree 819 (cf. the exercises in Section 6.2). We include a character-theoretic proof of this since the methods illustrate some important ideas in the theory of finite groups. The approach is based on M. Suzuki's seminal paper *The nonexistence of a certain type of simple group of odd order*, Proc. Amer. Math. Soc.,

8(1957), pp. 686–695, which treats much more general groups. Because we are dealing with a specific group order, our arguments are simpler and numerically more explicit, yet they retain some of the key ideas of Suzuki's work. Moreover, Suzuki's paper and its successor, *Finite groups in which the centralizer of any non-identity element is nilpotent*, by W. Feit, M. Hall and J. Thompson, Math. Zeit., 74(1960), pp. 1–17, are prototypes for the lengthy and difficult Feit–Thompson Theorem (cf. Section 3.4). Our discussion also conveys some of the flavor of these fundamental papers. In particular, each of these papers follows the basic development in which the structure and embedding of the Sylow subgroups is first determined and then character theory (with heavy reliance on induced characters) is applied.

For the remainder of this section we assume  $G$  is a simple group of order  $3^3 \cdot 7 \cdot 13 \cdot 409$ . We list some properties of  $G$  which may be verified using the methods stemming from Sylow's Theorem discussed in Section 6.2. The details are left as exercises.

- (1) Let  $q_1 = 3$ , let  $Q_1$  be a Sylow 3-subgroup of  $G$  and let  $N_1 = N_G(Q_1)$ . Then  $Q_1$  is an elementary abelian 3-group of order  $3^3$  and  $N_1$  is a Frobenius group of order  $3^3 \cdot 13$  with Frobenius kernel  $Q_1$  and with  $N_1/Q_1$  acting irreducibly by conjugation on  $Q_1$ .
- (2) Let  $q_2 = 7$ , let  $Q_2$  be a Sylow 7-subgroup of  $G$  and let  $N_2 = N_G(Q_2)$ . Then  $Q_2$  is cyclic of order 7 and  $N_2$  is the non-abelian group of order  $7 \cdot 3$  (so  $N_2$  is a Frobenius group with Frobenius kernel  $Q_2$ ).
- (3) Let  $q_3 = 13$ , let  $Q_3$  be a Sylow 11-subgroup of  $G$  and let  $N_3 = N_G(Q_3)$ . Then  $Q_3$  is cyclic of order 13 and  $N_3$  is the non-abelian group of order  $13 \cdot 3$  (so  $N_3$  is a Frobenius group with Frobenius kernel  $Q_3$ ).
- (4) Let  $q_4 = 409$ , let  $Q_4$  be a Sylow 409-subgroup of  $G$  and let  $N_4 = N_G(Q_4)$ . Then  $Q_4$  is cyclic of order 409 and  $N_4$  is the non-abelian group of order  $409 \cdot 3$  (so  $N_4$  is a Frobenius group with Frobenius kernel  $Q_4$ ).
- (5) Every nonidentity element of  $G$  has prime order and  $Q_i \cap Q_i^g = 1$  for every  $g \in G - N_i$ , for each  $i = 1, 2, 3, 4$ . The nonidentity conjugacy classes of  $G$  are:
  - (a) 2 classes of elements of order 3 (each of these classes has size  $7 \cdot 13 \cdot 409$ )
  - (b) 2 classes of elements of order 7 (each of these classes has size  $3^3 \cdot 13 \cdot 409$ )
  - (c) 4 classes of elements of order 13 (each of these classes has size  $3^3 \cdot 7 \cdot 409$ )
  - (d) 136 classes of elements of order 409 (each of these classes has size  $3^3 \cdot 7 \cdot 13$ ), and so there are 145 conjugacy classes in  $G$ .

Since each of the groups  $N_i$  is a Frobenius group satisfying the hypothesis of Proposition 13, the number of characters of  $N_i$  of degree  $> 1$  may be read off from that proposition:

- (i)  $N_1$  has 2 irreducible characters of degree 13
- (ii)  $N_2$  has 2 irreducible characters of degree 3
- (iii)  $N_3$  has 4 irreducible characters of degree 3
- (iv)  $N_4$  has 136 irreducible characters of degree 3.

From now on, to simplify notation, for any subgroup  $H$  of  $G$  and any generalized character  $\mu$  of  $H$  let

$$\mu^* = \text{Ind}_H^G(\mu)$$

so a star will always denote induction from a subgroup to the whole group  $G$  and the subgroup will be clear from the context.

The following lemma is a key point in the proof. It shows how the vanishing of induced characters described in Corollary 12 (together with the *trivial intersection* property of the Sylow subgroups  $Q_i$ , namely the fact that  $Q_i \cap Q_i^g = 1$  for all  $g \in G - N_G(Q_i)$ ) may be used to relate inner products of certain generalized characters to the inner products of their induced generalized characters. For these computations it is important that the generalized characters are zero on the identity (which explains why we are considering *differences* of characters of the same degree).

**Lemma 15.** For any  $i \in \{1, 2, 3, 4\}$  let  $q = q_i$ , let  $Q = Q_i$ , let  $N = N_i$  and let  $p = |N : Q|$ . Let  $\psi_1, \dots, \psi_4$  be any irreducible characters of  $N$  of degree  $p$  (not necessarily distinct) and let  $\alpha = \psi_1 - \psi_2$  and  $\beta = \psi_3 - \psi_4$ . Then  $\alpha$  and  $\beta$  are generalized characters of  $N$  which are zero on every element of  $N$  of order not equal to  $q$ . Furthermore,  $\alpha^*$  and  $\beta^*$  are generalized characters of  $G$  which are zero on every element of  $G$  of order not equal to  $q$  and

$$(\alpha^*, \beta^*)_G = (\alpha, \beta)_N$$

(where  $( , )_H$  denotes the usual Hermitian product of class functions computed in the group  $H$ ). In other words, induction from  $N$  to  $G$  is an inner product preserving map on such generalized characters  $\alpha, \beta$  of  $N$ .

*Proof:* By Proposition 13, there are nonprincipal characters  $\lambda_1, \dots, \lambda_4$  of  $Q$  of degree 1 such that  $\psi_j = \text{Ind}_Q^N(\lambda_j)$  for  $j = 1, \dots, 4$ . By Corollary 12 therefore, each  $\psi_j$  vanishes on  $N - Q$ , hence so do  $\alpha$  and  $\beta$ . Note that since  $\psi_j(1) = p$  for all  $j$  we have  $\alpha(1) = \beta(1) = 0$ . By the transitivity of induction,  $\psi_j^* = \text{Ind}_N^G(\psi_j) = \text{Ind}_Q^G(\lambda_j)$  for all  $j$ . Again by Corollary 12 applied to the latter induced character we see that  $\psi_j^*$  vanishes on all elements not conjugate in  $G$  to some element of  $Q$ , hence so do both  $\alpha^*$  and  $\beta^*$ . Since the induced characters  $\psi_j^*$  all have degree  $|G : Q|$ , the generalized characters  $\alpha^*$  and  $\beta^*$  are zero on the identity. Thus  $\alpha^*$  and  $\beta^*$  vanish on all elements of  $G$  which are not of order  $q$ . Finally, if  $g_1, \dots, g_m$  are representatives for the left cosets of  $N$  in  $G$  with  $g_1 = 1$ , then because  $Q \cap Q^{g_k} = 1$  for all  $k > 1$  (by (5) above), it follows immediately from the formula for induced (generalized) characters that  $\alpha^*(x) = \alpha(x)$  and  $\beta^*(x) = \beta(x)$  for all nonidentity elements  $x \in Q$  (i.e., for all elements  $x \in N$  of order  $q$ ). Furthermore, by Sylow's Theorem every element of  $G$  of order  $q$  lies in a conjugate of  $Q$ , hence the collection of  $G$ -conjugates of the set  $Q - \{1\}$  partition the elements of order  $q$  in  $G$  into  $|G : N|$  disjoint subsets. Since  $\alpha^*$  and  $\beta^*$  are class functions on  $G$ , the sum of  $\alpha^*(x)\overline{\beta^*(x)}$  as  $x$  runs over any of these subsets is the same. These facts imply

$$\begin{aligned} (\alpha^*, \beta^*)_G &= \frac{1}{|G|} \sum_{x \in G} \alpha^*(x)\overline{\beta^*(x)} \\ &= \frac{1}{|G|} \sum_{\substack{x \in G \\ |x|=q}} \alpha^*(x)\overline{\beta^*(x)} \\ &= \frac{1}{|G|} \sum_{\substack{x \in N \\ |x|=q}} |G : N| \alpha^*(x)\overline{\beta^*(x)} \end{aligned}$$

$$= \frac{1}{|N|} \sum_{x \in N} \alpha(x) \overline{\beta(x)} = (\alpha, \beta)_N.$$

This completes the proof.

The next lemma sets up a correspondence between the irreducible characters of  $N_i$  of degree  $> 1$  and some nonprincipal irreducible characters of  $G$ .

**Lemma 16.** For any  $i \in \{1, 2, 3, 4\}$  let  $q = q_i$ , let  $Q = Q_i$ , let  $N = N_i$  and let  $p = |N : Q|$ . Let  $\psi_1, \dots, \psi_k$  be the distinct irreducible characters of  $N$  of degree  $p$ . Then there are distinct irreducible characters  $\chi_1, \dots, \chi_k$  of  $G$ , all of which have the same degree, and a fixed sign  $\epsilon = \pm 1$  such that  $\psi_1^* - \psi_j^* = \epsilon(\chi_1 - \chi_j)$  for all  $j = 2, 3, \dots, k$ .

*Proof:* Let  $\alpha_j = \psi_1 - \psi_j$  for  $j = 2, 3, \dots, k$  so  $\alpha_j$  satisfies the hypothesis of Lemma 15. Since  $\psi_1 \neq \psi_j$ , by Lemma 15

$$2 = \|\alpha_j\|^2 = (\alpha_j, \alpha_j)_N = (\alpha_j^*, \alpha_j^*)_G = \|\alpha_j^*\|^2$$

for all  $j$ . Thus  $\alpha_j^*$  must have two distinct irreducible characters of  $G$  as its irreducible constituents. Since  $\alpha_j^*(1) = 0$  it must be a difference of two distinct irreducible characters, both of which have the same degree. In particular, the lemma holds if  $k = 2$  (which is the case for  $q = 3$  and  $q = 7$ ). Assume therefore that  $k > 2$  and write

$$\begin{aligned}\alpha_2^* &= \psi_1^* - \psi_2^* = \epsilon(\chi - \chi') \\ \alpha_3^* &= \psi_1^* - \psi_3^* = \epsilon'(\theta - \theta')\end{aligned}$$

for some irreducible characters  $\chi, \chi', \theta, \theta'$  of  $G$  and some signs  $\epsilon, \epsilon'$ . As proved above,  $\chi \neq \chi'$  and  $\theta \neq \theta'$ . Interchanging  $\theta$  and  $\theta'$  if necessary, we may assume  $\epsilon = \epsilon'$ . Thus

$$\alpha_3^* - \alpha_2^* = \psi_2^* - \psi_3^* = \epsilon(\theta - \theta' - \chi + \chi').$$

By Lemma 15,  $\psi_2^* - \psi_3^* = (\psi_2 - \psi_3)^*$  also has exactly two distinct irreducible constituents, hence either  $\theta = \chi$  or  $\theta' = \chi'$ . Replacing  $\epsilon$  by  $-\epsilon$  if necessary we may assume that  $\theta = \chi$  so that now we have

$$\begin{aligned}\alpha_2^* &= \psi_1^* - \psi_2^* = \epsilon(\chi - \chi') \\ \alpha_3^* &= \psi_1^* - \psi_3^* = \epsilon(\chi - \theta')\end{aligned}$$

where  $\chi, \chi'$  and  $\theta$  are distinct irreducible characters of  $G$  and the sign  $\epsilon$  is determined. Label  $\chi = \chi_1, \chi' = \chi_2$  and  $\theta = \chi_3$ . Now one similarly checks that for each  $j \geq 3$  there is an irreducible character  $\chi_j$  of  $G$  such that

$$\alpha_j^* = \psi_1^* - \psi_j^* = \epsilon(\chi_1 - \chi_j)$$

and  $\chi_1, \dots, \chi_k$  are distinct. Since all  $\chi_j$ 's have the same degree as  $\chi_1$ , the proof is complete.

We remark that it need not be the case that  $\chi_j = \psi_j^*$  for any  $j$ , but only that the differences of irreducible characters of  $N$  induce to differences of irreducible characters of  $G$ .

The irreducible characters  $\chi_j$  of  $G$  obtained via Lemma 16 are called *exceptional characters* associated to  $Q$ .

**Lemma 17.** The exceptional characters associated to  $Q_i$  are all distinct from the exceptional characters associated to  $Q_j$  for  $i$  and  $j$  distinct elements of  $\{1, 2, 3, 4\}$ .

*Proof:* Let  $\chi$  be an exceptional character associated to  $Q_i$  and let  $\theta$  be an exceptional character associated to  $Q_j$ . By construction, there are distinct irreducible characters  $\psi$  and  $\psi'$  of  $Q_i$  such that  $\psi^* - \psi'^* = \chi - \chi'$  and there are distinct irreducible characters  $\lambda$  and  $\lambda'$  of  $Q_j$  such that  $\lambda^* - \lambda'^* = \theta - \theta'$ . Let  $\alpha = \psi - \psi'$  and let  $\beta = \lambda - \lambda'$ . By Lemma 15,  $\alpha^*$  is zero on all elements of  $G$  whose order is not equal to  $q_i$  (including the identity) and  $\beta^*$  is zero on all elements of  $G$  whose order is not equal to  $q_j$ . Thus clearly  $(\alpha^*, \beta^*) = 0$ . It follows easily that the two irreducible constituents of  $\alpha^*$  are pairwise orthogonal to those of  $\beta^*$  as well. This establishes the lemma.

It is now easy to show that such a simple group  $G$  does not exist. By Lemma 16 and properties (i) to (iv) of  $G$  we can count the number of exceptional characters:

- (i) there are 2 exceptional characters associated to  $Q_1$
- (ii) there are 2 exceptional characters associated to  $Q_2$
- (iii) there are 4 exceptional characters associated to  $Q_3$
- (iv) there are 136 exceptional characters associated to  $Q_4$ .

Denote the common degree of the exceptional characters associated to  $Q_i$  by  $d_i$  for  $i = 1, \dots, 4$ . By Lemma 17, the exceptional characters account for 144 nonprincipal irreducible characters of  $G$  hence these, together with the principal character, are all the irreducible characters of  $G$  (the number of conjugacy classes of  $G$  is 145). The sum of the squares of the degrees of the irreducible characters is the order of  $G$ :

$$1 + 2d_1^2 + 2d_2^2 + 4d_3^2 + 136d_4^2 = 1004913.$$

Simplifying this, we obtain

$$d_1^2 + d_2^2 + 2d_3^2 + 68d_4^2 = 502456. \quad (19.4)$$

Finally, since each nonprincipal irreducible representation of the simple group  $G$  is faithful and since the smallest degree of a faithful representation of  $N_1$  is 13, each  $d_i \geq 13$ . Since  $d_4 < \sqrt{502456}/68 < 86$  and  $d_4$  divides  $|G|$ , it follows that

$$d_4 \in \{13, 21, 27, 39, 63\}.$$

Furthermore, each  $d_i \mid |G|$  by Corollary 5 and so there are a small number of possibilities for each  $d_i$ . One now checks that equation (4) has no solution (this is particularly easy to do by computer). This contradiction completes the proof.

## EXERCISES

Throughout the exercises all representations are over the complex numbers.

1. Let  $G = S_3$ , let  $H = A_3$  and let  $V$  be the 3-dimensional  $CH$ -module which affords the natural permutation representation of  $A_3$ . More explicitly, let  $V$  have basis  $e_1, e_2, e_3$  and let  $\sigma \in A_3$  act on  $V$  by  $\sigma e_i = e_{\sigma(i)}$ . Let 1 and  $(1\ 2)$  be coset representatives for the left cosets of  $A_3$  in  $S_3$  and write out the explicit matrices described in Theorem 11 for the action of  $S_3$  on the induced module  $W$ , for each of the elements of  $S_3$ .
2. In each of parts (a) to (f) a character  $\psi$  of a subgroup  $H$  of a particular group  $G$  is specified. Compute the values of the induced character  $\text{Ind}_H^G(\psi)$  on all the conjugacy classes of  $G$  and use the character tables in Section 1 to write  $\text{Ind}_H^G(\psi)$  as a sum of irreducible characters:

- (a)  $\psi$  is the unique nonprincipal degree 1 character of the subgroup  $\langle (1\ 2) \rangle$  of  $S_3$
- (b)  $\psi$  is the degree 1 character of the subgroup  $\langle r \rangle$  of  $D_8$  defined by  $\psi(r) = i$ , where  $i \in \mathbb{C}$  is a square root of  $-1$
- (c)  $\psi$  is the degree 1 character of the subgroup  $\langle r \rangle$  of  $D_8$  defined by  $\psi(r) = -1$
- (d)  $\psi$  is any of the nonprincipal degree 1 characters of the subgroup  $V_4 = \langle (1\ 2), (3\ 4) \rangle$  of  $S_4$
- (e)  $\psi = \chi_4$  is the first of the two characters of degree 3 in the character table of  $H = S_4$  in Section 1 and  $H$  is a subgroup of  $G = S_5$
- (f)  $\psi$  is any of the nonprincipal degree 1 characters of the subgroup  $V_4 = \langle (1\ 2), (3\ 4) \rangle$  of  $S_5$ .
3. Use Proposition 13 to explicitly write out the character table of each of the following groups:
- the dihedral group of order 10
  - the non-abelian group of order 57
  - the non-abelian group of order 56 which has a normal, elementary abelian Sylow 2-subgroup.
4. Let  $H$  be a subgroup of  $G$ , let  $\varphi$  be a representation of  $H$  and suppose that  $N$  is a normal subgroup of  $G$  with  $N \leq H$  and  $N$  contained in the kernel of  $\varphi$ . Prove that  $N$  is also contained in the kernel of the induced representation of  $\varphi$ .
5. Let  $N$  be a normal subgroup of  $G$  and let  $\psi_1$  be the principal character of  $N$ . Let  $\Psi$  be the induced character  $\text{Ind}_N^G(\psi_1)$  so that by the preceding exercise we may consider  $\Psi$  as the character of a representation of  $G/N$ . Prove that  $\Psi$  is the character of the regular representation of  $G/N$ .
6. Let  $Z$  be any subgroup of the center of  $G$ , let  $|G : Z| = m$  and let  $\psi$  be a character of  $Z$ . Prove that
- $$\text{Ind}_Z^G(\psi)(g) = \begin{cases} m\psi(g) & \text{if } g \in Z \\ 0 & \text{if } g \notin Z. \end{cases}$$
7. Let  $\varphi$  be a matrix representation of the subgroup  $H$  of  $G$  and define matrices  $\Phi(g)$  for every  $g \in G$  by the displayed formula in the statement of Theorem 11. Prove directly that  $\Phi$  is a representation by showing that  $\Phi(xy) = \Phi(x)\Phi(y)$  for all  $x, y \in G$ .
8. Let  $G$  be a Frobenius group with Frobenius kernel  $Q$ . Assume that both  $Q$  and  $G/Q$  are abelian but  $G$  is not abelian (i.e.,  $G \neq Q$ ). Let  $|Q| = n$  and  $|G : Q| = m$ .
- Prove that  $G/Q$  is cyclic and show that  $G = QC$  for some cyclic subgroup  $C$  of  $G$  with  $C \cap Q = 1$  (i.e.,  $G$  is a semidirect product of  $Q$  and  $C$  and  $|C| = m$ ). [Let  $q$  be a prime divisor of  $n$  and let  $G/Q$  act by conjugation on the elementary abelian  $q$ -group  $\{h \in Q \mid h^q = 1\}$ . Apply Exercise 14(e) of Section 18.1 and the definition of a Frobenius group to an irreducible constituent of this  $\mathbb{F}_q G/Q$ -module.]
  - Prove that  $n$  and  $m$  are relatively prime. [If a prime  $p$  divides both the order and index of  $Q$ , let  $P$  be a Sylow  $p$ -subgroup of  $G$ . Then  $P \cap Q \trianglelefteq P$  and  $P \cap Q$  is a Sylow  $p$ -subgroup of  $Q$ . Consider the centralizer in  $G$  of the subgroup  $Z(P) \cap Q$  (this intersection is nontrivial by Theorem 1 of Section 6.1).]
  - Show that  $G$  has no elements of order  $qp$ , where  $q$  is any nontrivial divisor of  $n$  and  $p$  is any nontrivial divisor of  $m$ . [Argue as in Proposition 13.]
  - Prove that the number of nonidentity conjugacy classes of  $G$  contained in  $Q$  is  $(n-1)/m$  and that each of these classes has size  $m$ . [Argue as in Proposition 13.]
  - Prove that no two distinct elements of  $C$  are conjugate in  $G$ . Deduce that the nonidentity elements of  $C$  are representatives for  $m-1$  distinct conjugacy classes of  $G$  and that each of these classes has size  $n$ . Deduce then that every element of  $G - Q$

- is conjugate to some element of  $C$  and that  $G$  has  $m + (n - 1)/m$  conjugacy classes.
- (f) Prove that  $G' = Q$  and deduce that  $G$  has  $m$  distinct characters of degree 1. [To show  $Q \leq G'$  let  $C = \langle x \rangle$  and argue that the map  $h \mapsto [h, x] = x^{-1}h^{-1}xh$  is a homomorphism from  $Q$  to  $Q$  whose kernel is trivial, hence this map is surjective.]
- (g) Show that if  $\psi$  is any nonprincipal irreducible character of  $Q$ , then  $\text{Ind}_Q^G(\psi)$  is an irreducible character of  $G$ . Show that every irreducible character of  $G$  of degree  $> 1$  is equal to  $\text{Ind}_Q^G(\psi)$  for some nonprincipal irreducible character  $\psi$  of  $Q$ . Deduce that every irreducible character of  $G$  has degree either 1 or  $m$  and the number of irreducible characters of degree  $m$  is  $(n - 1)/m$ . [Check that the proof of Proposition 13(3) establishes this more general result with the appropriate changes to the numbers involved.]
9. Use the preceding exercise to explicitly write out the character table of  $\{(1\ 2\ 3\ 4\ 5), (2\ 3\ 5\ 4)\}$ , which is the normalizer in  $S_5$  of a Sylow 5-subgroup (this group is a Frobenius group of order 20).
10. Let  $N$  be a normal subgroup of  $G$ , let  $\psi$  be a character of  $N$  and let  $g \in G$ . Define  $\psi^g$  by  $\psi^g(h) = \psi(ghg^{-1})$  for all  $h \in N$ .
- Prove that  $\psi^g$  is a character of  $N$  ( $\psi$  and  $\psi^g$  are called *G-conjugate* characters of  $N$ ). Prove that  $\psi^g$  is irreducible if and only if  $\psi$  is irreducible.
  - Prove that the map  $\psi \mapsto \psi^g$  is a right group action of  $G$  on the set of characters of  $N$  and  $N$  is in the kernel of this action.
  - Prove that if  $\psi_1$  and  $\psi_2$  are *G-conjugate* characters of  $N$ , then  $\text{Ind}_N^G(\psi_1) = \text{Ind}_N^G(\psi_2)$ . Prove also that if  $\psi_1$  and  $\psi_2$  are characters of  $N$  that are not *G-conjugate* then  $\text{Ind}_N^G(\psi_1) \neq \text{Ind}_N^G(\psi_2)$ . [Use the argument in the proof of Proposition 13(3).]
11. Show that if  $G = A_4$  and  $N = V_4$  is its Sylow 2-subgroup then any two nonprincipal irreducible characters of  $N$  are *G-conjugate* (cf. the preceding exercise).
12. Let  $G = D_{2n}$  be presented by its usual generators and relations. Prove that if  $\psi$  is any degree 1 character of  $H = \langle r \rangle$  such that  $\psi \neq \psi^s$ , then  $\text{Ind}_H^G(\psi)$  is an irreducible character of  $D_{2n}$ . Show that every irreducible character of  $D_{2n}$  is the induced character of some degree 1 character of  $\langle r \rangle$ .
13. Prove both parts of Proposition 14.
14. Prove the following result known as *Frobenius Reciprocity*: let  $H \leq G$ , let  $\psi$  be any character of  $H$  and let  $\chi$  be any character of  $G$ . Then

$$(\psi, \chi|_H)_H = (\text{Ind}_H^G(\psi), \chi)_G.$$

[Expand the right hand side using the formula for the induced character  $\text{Ind}_H^G(\psi)$  or follow the proof of Shapiro's Lemma in Section 17.2.]

15. Assume  $G$  were a simple group of order  $3^3 \cdot 7 \cdot 13 \cdot 409$  whose Sylow subgroups and their normalizers are described by properties (1) to (5) in this section. Prove that the permutation character of degree 819 obtained from the action of  $G$  on the left cosets of the subgroup  $N_4$  decomposes as  $\chi_0 + \gamma + \gamma'$ , where  $\chi_0$  is the principal character of  $G$  and  $\gamma$  and  $\gamma'$  are distinct irreducible characters of  $G$  of degree 409. [Use Exercise 9 in Section 18.3 to show that this permutation character  $\pi$  has  $\|\pi\|^2 = 3$ .]

## APPENDIX I

# Cartesian Products and Zorn's Lemma

Section 1 of this appendix contains the definition of the Cartesian product of an arbitrary collection of sets. In the text we shall primarily be interested in products of finitely many (or occasionally countably many) sets. We indicate how the general definition agrees with the familiar “ordered  $n$ -tuple” notion of a Cartesian product in these cases. Section 2 contains a discussion of Zorn’s Lemma and related topics.

### 1. CARTESIAN PRODUCTS

A set  $I$  is called an *indexing set* or *index set* if the elements of  $I$  are used to index some collection of sets. In particular, if  $A$  and  $I$  are sets, we can form the collection  $\{A_i \mid i \in I\}$  by specifying that  $A_i = A$  for all  $i \in I$ . Thus *any* set can be an indexing set; we use this term to emphasize that the elements are used as indices.

#### Definition.

- (1) Let  $I$  be an indexing set and let  $\{A_i \mid i \in I\}$  be a collection of sets. A *choice function* is any function

$$f : I \rightarrow \bigcup_{i \in I} A_i$$

such that  $f(i) \in A_i$  for all  $i \in I$ .

- (2) Let  $I$  be an indexing set and for all  $i \in I$  let  $A_i$  be a set. The *Cartesian product* of  $\{A_i \mid i \in I\}$  is the set of all choice functions from  $I$  to  $\bigcup_{i \in I} A_i$  and is denoted by  $\prod_{i \in I} A_i$  (where if either  $I$  or any of the sets  $A_i$  are empty the Cartesian product is the empty set). The elements of this Cartesian product are written as  $\prod_{i \in I} a_i$ , where this denotes the choice function  $f$  such that  $f(i) = a_i$  for each  $i \in I$ .
- (3) For each  $j \in I$  the set  $A_j$  is called the  $j^{\text{th}}$  *component* of the Cartesian product  $\prod_{i \in I} A_i$  and  $a_j$  is the  $j^{\text{th}}$  *coordinate* of the element  $\prod_{i \in I} a_i$ .
- (4) For  $j \in I$  the *projection map* of  $\prod_{i \in I} A_i$  onto the  $j^{\text{th}}$  coordinate,  $A_j$ , is defined by  $\prod_{i \in I} a_i \mapsto a_j$ .

Each choice function  $f$  in the Cartesian product  $\prod_{i \in I} A_i$  may be thought of as a way of “choosing” an element  $f(i)$  from each set  $A_i$ .

If  $I = \{1, 2, \dots, n\}$  for some  $n \in \mathbb{Z}^+$  and if  $f$  is a choice function from  $I$  to  $A_1 \cup \dots \cup A_n$ , where each  $A_i$  is nonempty, we can associate to  $f$  a unique (ordered)  $n$ -tuple:

$$f \rightarrow (f(1), f(2), \dots, f(n)).$$

Note that by definition of a choice function,  $f(i) \in A_i$  for all  $i$ , so the  $n$ -tuple above has an element of  $A_i$  in the  $i^{\text{th}}$  position for each  $i$ .

Conversely, given an  $n$ -tuple  $(a_1, a_1, \dots, a_n)$ , where  $a_i \in A_i$  for all  $i \in I$ , there is a unique choice function,  $f$ , from  $I$  to  $\bigcup_{i \in I} A_i$  associated to it, namely

$$f(i) = a_i, \quad \text{for all } i \in I.$$

It is clear that this map from  $n$ -tuples to choice functions is the inverse to the map described in the preceding paragraph. Thus *there is a bijection between ordered  $n$ -tuples and elements of  $\prod_{i \in I} A_i$* . Henceforth when  $I = \{1, 2, \dots, n\}$  we shall write

$$\prod_{i=1}^n A_i \quad \text{or} \quad A_1 \times A_2 \times \cdots \times A_n$$

for the Cartesian product and we shall describe the elements as ordered  $n$ -tuples.

If  $I = \mathbb{Z}^+$ , we shall similarly write:  $\prod_{i=1}^{\infty} A_i$  or  $A_1 \times A_2 \times \cdots$  for the Cartesian product of the  $A_i$ 's. We shall write the elements as ordered tuples:  $(a_1, a_2, \dots)$ , i.e., as infinite sequences whose  $i^{\text{th}}$  terms are in  $A_i$ .

Note that when  $I = \{1, 2, \dots, n\}$  or  $I = \mathbb{Z}^+$  we have used the natural ordering on  $I$  to arrange the elements of our Cartesian products into  $n$ -tuples. Any other ordering of  $I$  (or any ordering on a finite or countable index set) gives a different representation of the elements of the same Cartesian product.

## Examples

- (1)  $A \times B = \{(a, b) \mid a \in A, b \in B\}$ .
- (2)  $\mathbb{R}^n = \mathbb{R} \times \mathbb{R} \times \cdots \times \mathbb{R}$  ( $n$  factors) is the usual set of  $n$ -tuples with real number entries, Euclidean  $n$ -space.
- (3) Suppose  $I = \mathbb{Z}^+$  and  $A_i$  is the same set  $A$ , for all  $i \in I$ . The Cartesian product  $\prod_{i \in \mathbb{Z}^+} A$  is the set of all (infinite) sequences  $a_1, a_2, a_3, \dots$  of elements of  $A$ . In particular, if  $A = \mathbb{R}$ , then the Cartesian product  $\prod_{i \in \mathbb{Z}^+} \mathbb{R}$  is the set of all real sequences.
- (4) Suppose  $I$  is any indexing set and  $A_i$  is the same set  $A$ , for all  $i \in I$ . The Cartesian product  $\prod_{i \in I} A$  is just the set of all functions from  $I$  to  $A$ , where the function  $f : I \rightarrow A$  corresponds to the element  $\prod_{i \in I} f(i)$  in the Cartesian product. This Cartesian product is often (particularly in topology books) denoted by  $A^I$ . Note that for each fixed  $j \in I$  the projection map onto the  $j^{\text{th}}$  coordinate sends the function  $f$  to  $f(j)$ , i.e., is evaluation at  $j$ .
- (5) Let  $R$  be a ring and let  $x$  be an indeterminate over  $R$ . The definition of the ring  $R[x]$  of polynomials in  $x$  with coefficients from  $R$  may be given in terms of Cartesian products rather than in the more intuitive and familiar terms of “formal sums” (in Chapters 7 and 9 we introduced them in the latter form since this is the way we envision and work with them). Let  $I$  be the indexing set  $\mathbb{Z}^+ \cup \{0\}$  and let  $R[x]$  be the subset of the Cartesian product  $\prod_{i=0}^{\infty} R$  consisting of elements  $(a_0, a_1, a_2, \dots)$  such that only finitely many of the  $a_i$ 's are nonzero. If  $(a_0, a_1, a_2, \dots, a_n, 0, 0, \dots)$  is such a sequence we represent it by the more familiar “formal sum”  $\sum_{i=0}^n a_i x^i$ . Addition and multiplication of these sequences is defined so that the usual rules for addition and multiplication of polynomials hold.

**Proposition 1.** Let  $I$  be a nonempty countable set and for each  $i \in I$  let  $A_i$  be a set. The cardinality of the Cartesian product is the product of the cardinalities of the sets  $A_i$ , i.e.,

$$|\prod_{i \in I} A_i| = \prod_{i \in I} |A_i|,$$

(where if some  $A_i$  is an infinite set or if  $I$  is infinite and an infinite number of  $A_i$ 's have cardinality  $\geq 2$ , both sides of this equality are infinity). In particular,

$$|A_1 \times A_2 \times \cdots \times A_n| = |A_1| \times |A_2| \times \cdots \times |A_n|.$$

*Proof:* In order to count the number of choice functions note that each  $i \in I$  may be mapped to any of the  $|A_i|$  elements of  $A_i$  and for  $i \neq j$  the values of choice functions at  $i$  and  $j$  may be chosen completely independently. Thus the number of choice functions is the product of the cardinalities of the  $A_i$ 's, as claimed.

For Cartesian products of finitely many sets,  $A_1 \times A_2 \times \cdots \times A_n$ , one can see this easily from the  $n$ -tuple representation: the elements of  $A_1 \times A_2 \times \cdots \times A_n$  are  $n$ -tuples  $(a_1, a_2, \dots, a_n)$  and each  $a_i$  may be chosen as any of the  $|A_i|$  elements of  $A_i$ . Since these choices are made independently for  $i \neq j$ , there are  $|A_1| \cdot |A_2| \cdots |A_n|$  elements in the Cartesian product.

## EXERCISE

1. Let  $I$  and  $J$  be any two indexing sets and let  $A$  be an arbitrary set. For any function  $\varphi : J \rightarrow I$  define

$$\varphi^* : \prod_{i \in I} A \rightarrow \prod_{j \in J} A \quad \text{by} \quad \varphi^*(f) = f \circ \varphi \quad \text{for all choice functions } f \in \prod_{i \in I} A.$$

- (a) Let  $I = \{1, 2\}$ , let  $J = \{1, 2, 3\}$  and let  $\varphi : J \rightarrow I$  be defined by  $\varphi(1) = 2$ ,  $\varphi(2) = 2$  and  $\varphi(3) = 1$ . Describe explicitly how a 3-tuple in  $A \times A \times A$  maps to an ordered pair in  $A \times A$  under this  $\varphi^*$ .
- (b) Let  $I = J = \{1, 2, \dots, n\}$  and assume  $\varphi$  is a permutation of  $I$ . Describe in terms of  $n$ -tuples in  $A \times A \times \cdots \times A$  the function  $\varphi^*$ .

## 2. PARTIALLY ORDERED SETS AND ZORN'S LEMMA

We shall have occasion to use Zorn's Lemma as a form of "infinite induction" in a few places in the text where it is desirable to know the existence of some set which is *maximal* with respect to certain specified properties. For example, Zorn's Lemma is used to show that every vector space has a basis. In this situation a basis of a vector space  $V$  is a subset of  $V$  which is maximal as a set consisting of linearly independent vectors (the maximality ensures that these vectors span  $V$ ). For finite dimensional spaces this can be proved by induction; however, for spaces of arbitrary dimension Zorn's Lemma is needed to establish this. By having results which hold in full generality the theory often becomes a little neater in places, although the main results of the text do not require its use.

A specific instance in the text where a maximal object which helps to simplify matters is constructed by Zorn's Lemma is the algebraic closure of a field. An algebraic closure of a field  $F$  is an extension of  $F$  which is maximal among any collection of algebraic extensions. Such a field contains (up to isomorphism) all elements which are algebraic over  $F$ , hence all manipulations involving such algebraic elements can be effected in this one larger field. In any particular situation the use of an algebraic closure can be avoided by adjoining the algebraic elements involved to the base field  $F$ , however this becomes tedious (and often obscures matters) in complicated proofs. For the specific fields appearing as examples in this text the use of Zorn's Lemma to construct an algebraic closure can be avoided (for example, the construction of an algebraic closure of any subfield of the complex numbers or of any finite field does not require it).

The first example of the use of Zorn's Lemma appears in the proof of Proposition 11 in Section 7.4.

In order to state Zorn's Lemma we need some terminology.

**Definition.** A *partial order* on a nonempty set  $A$  is a relation  $\leq$  on  $A$  satisfying

- (1)  $x \leq x$  for all  $x \in A$  (reflexive),
- (2) if  $x \leq y$  and  $y \leq x$  then  $x = y$  for all  $x, y \in A$  (antisymmetric),
- (3) if  $x \leq y$  and  $y \leq z$  then  $x \leq z$  for all  $x, y, z \in A$  (transitive).

We shall usually say that  $A$  is a partially ordered set under the ordering  $\leq$  or that  $A$  is partially ordered by  $\leq$ .

**Definition.** Let the nonempty set  $A$  be partially ordered by  $\leq$ .

- (1) A subset  $B$  of  $A$  is called a *chain* if for all  $x, y \in B$ , either  $x \leq y$  or  $y \leq x$ .
- (2) An *upper bound* for a subset  $B$  of  $A$  is an element  $u \in A$  such that  $b \leq u$ , for all  $b \in B$ .
- (3) A *maximal element* of  $A$  is an element  $m \in A$  such that if  $m \leq x$  for any  $x \in A$ , then  $m = x$ .

In the literature a chain is also called a *tower* or called a *totally ordered* or *linearly ordered* or *simply ordered* subset.

Some examples below highlight the distinction between upper bounds and maximal elements. Also note that if  $m$  is a *maximal element* of  $A$ , it is not necessarily the case that  $x \leq m$  for all  $x \in A$  (i.e.,  $m$  is not necessarily a *maximum element*).

## Examples

- (1) Let  $A$  be the power set (i.e., set of all subsets) of some set  $X$  and  $\leq$  be set containment:  $\subseteq$ . Notice that this is only a *partial* ordering since some subsets of  $X$  may not be comparable, e.g. singletons: if  $x \neq y$  then  $\{x\} \not\subseteq \{y\}$  and  $\{y\} \not\subseteq \{x\}$ . In this situation an example of a chain is a collection of subsets of  $X$  such as

$$X_1 \subseteq X_2 \subseteq X_3 \subseteq \dots$$

Any subset  $B$  of  $A$  has an upper bound,  $b$ , namely,

$$b = \bigcup_{x \in B} x.$$

This partially ordered set  $A$  has a (unique) maximal element,  $X$ .

In many instances the set  $A$  consists of some (but not necessarily all) subsets of a set  $X$  (i.e.,  $A$  is a subset of the power set of  $X$ ) and with the ordering on  $A$  again being inclusion. The existence of upper bounds and maximal elements depends on the nature of  $A$ .

- (2) Let  $A$  be the collection of all *proper* subsets of  $\mathbb{Z}^+$  ordered under  $\subseteq$ . In this situation, chains need not have maximal elements, e.g. the chain

$$\{1\} \subseteq \{1, 2\} \subseteq \{1, 2, 3\} \subseteq \dots$$

does not have an upper bound. The set  $A$  does have maximal elements: for example  $\mathbb{Z}^+ - \{n\}$  is a maximal element of  $A$  for any  $n \in \mathbb{Z}^+$ .

- (3) Let  $A = \mathbb{R}$  under the usual  $\leq$  relation. In this example every subset of  $A$  is a chain (including  $A$  itself). The notion of a subset of  $A$  having an upper bound is the same as the usual notion of a subset of  $\mathbb{R}$  being bounded above by some real number (so some sets, such as intervals of finite length, have upper bounds and others, such as the set of positive reals, do not). The set  $A$  does not have a maximal element.

**Zorn's Lemma** If  $A$  is a nonempty partially ordered set in which every chain has an upper bound then  $A$  has a maximal element.

It is a nontrivial result that *Zorn's Lemma is independent of the usual (Zermelo–Fraenkel) axioms of set theory*<sup>1</sup> in the sense that if the axioms of set theory are consistent,<sup>2</sup> then so are these axioms together with Zorn's Lemma; and if the axioms of set theory are consistent, then so are these axioms together with the *negation* of Zorn's Lemma. The use of the term “lemma” in Zorn's Lemma is historical.

For the sake of completeness (and to relate Zorn's Lemma to formulations found in other courses) we include two other equivalent formulations of Zorn's Lemma.

**The Axiom of Choice** The Cartesian product of any nonempty collection of nonempty sets is nonempty. In other words, if  $I$  is any nonempty (indexing) set and  $A_i$  is a nonempty set for all  $i \in I$ , then there exists a choice function from  $I$  to  $\bigcup_{i \in I} A_i$ .

**Definition.** Let  $A$  be a nonempty set. A *well ordering* on  $A$  is a total ordering on  $A$  such that every nonempty subset of  $A$  has a minimum (or smallest) element, i.e., for each nonempty  $B \subseteq A$  there is some  $s \in B$  such that  $s \leq b$ , for all  $b \in B$ .

**The Well Ordering Principle** Every nonempty set  $A$  has a well ordering.

**Theorem 2.** Assuming the usual (Zermelo–Fraenkel) axioms of set theory, the following are equivalent:

- (1) Zorn's Lemma
- (2) the Axiom of Choice
- (3) the Well Ordering Principle.

*Proof:* This follows from elementary set theory. We refer the reader to *Real and Abstract Analysis* by Hewitt and Stromberg, Springer-Verlag, 1965, Section 3 for these equivalences and some others.

---

<sup>1</sup>See P.J. Cohen's papers in: Proc. Nat. Acad. Sci., 50(1963), and 51(1964).

<sup>2</sup>This is not known to be the case!

## EXERCISES

1. Let  $A$  be the collection of all finite subsets of  $\mathbb{R}$  ordered by inclusion. Discuss the existence (or nonexistence) of upper bounds, minimal and maximal elements (where minimal elements are defined analogously to maximal elements). Explain why this is not a well ordering.
2. Let  $A$  be the collection of all infinite subsets of  $\mathbb{R}$  ordered by inclusion. Discuss the existence (or nonexistence) of upper bounds, minimal and maximal elements. Explain why this is not a well ordering.
3. Show that the following partial orderings on the given sets are not well orderings:
  - (a)  $\mathbb{R}$  under the usual relation  $\leq$ .
  - (b)  $\mathbb{R}^+$  under the usual relation  $\leq$ .
  - (c)  $\mathbb{R}^+ \cup \{0\}$  under the usual relation  $\leq$ .
  - (d)  $\mathbb{Z}$  under the usual relation  $\leq$ .
4. Show that  $\mathbb{Z}^+$  is well ordered under the usual relation  $\leq$ .

## APPENDIX II

# Category Theory

Category theory provides the language and the mathematical foundations for discussing properties of large classes of mathematical objects such as the class of “all sets” or “all groups” while circumventing problems such as Russell’s Paradox. In this framework one may explore the commonality across classes of concepts and methods used in the study of each class: homomorphisms, isomorphisms, etc., and one may introduce tools for studying relations between classes: functors, equivalence of categories, etc. One may then formulate precise notions of a “natural” transformation and “natural” isomorphism, both within a given class or between two classes. (In the text we described “natural” as being “coordinate free.”) A prototypical example of natural isomorphisms within a class is the isomorphism of an arbitrary finite dimensional vector space with its double dual in Section 11.3. In fact one of the primary motivations for the introduction of categories and functors by S. Eilenberg and S. MacLane in 1945 was to give a precise meaning to the notions of “natural” in cases such as this. Category theory has also played a foundational role for formalizing new concepts such as schemes (cf. Section 15.5) that are fundamental to major areas of contemporary research (e.g., algebraic geometry). Pioneering work of this nature was done by A. Grothendieck, K. Morita and others.

Our treatment of category theory should be viewed more as an introduction to some of the basic language. Since we have not discussed the Zermelo–Fraenkel axioms of set theory or the Gödel–Bernays axioms of classes we make no mention of the foundations of category theory. To remain consistent with the set theory axioms, however, we implicitly assume that there is a *universe* set  $\mathbf{U}$  which contains all the sets, groups, rings, etc. that one would encounter in “ordinary” mathematics (so that the category of “all sets” implicitly means “all sets in  $\mathbf{U}$ ”). The reader is referred to books on set theory, logic, or category theory such as *Categories for the Working Mathematician* by S. MacLane, Springer–Verlag, 1971 for further study.

We have organized this appendix so that wherever possible the examples of each new concept use terminology and structures in the order that these appear in the body of the text. For instance, the first example of a functor involves sets and groups, the second example uses rings, etc. In this way the appendix may be read early on in one’s study, and a greater appreciation may be gained through rereading the examples as one becomes conversant with a wider variety of mathematical structures.

### 1. CATEGORIES AND FUNCTORS

We begin with the basic concept of this appendix.

**Definition.** A *category*  $\mathbf{C}$  consists of a class of *objects* and sets of *morphisms* between those objects. For every ordered pair  $A, B$  of objects there is a set  $\text{Hom}_{\mathbf{C}}(A, B)$  of

morphisms from  $A$  to  $B$ , and for every ordered triple  $A, B, C$  of objects there is a *law of composition* of morphisms, i.e., a map

$$\text{Hom}_C(A, B) \times \text{Hom}_C(B, C) \longrightarrow \text{Hom}_C(A, C)$$

where  $(f, g) \mapsto gf$ , and  $gf$  is called the composition of  $g$  with  $f$ . The objects and morphism satisfy the following axioms: for objects  $A, B, C$  and  $D$

- (i) if  $A \neq B$  or  $C \neq D$ , then  $\text{Hom}_C(A, B)$  and  $\text{Hom}_C(C, D)$  are disjoint sets,
- (ii) composition of morphisms is associative, i.e.,  $h(gf) = (hg)f$  for every  $f$  in  $\text{Hom}_C(A, B)$ ,  $g$  in  $\text{Hom}_C(B, C)$  and  $h$  in  $\text{Hom}_C(C, D)$ ,
- (iii) each object has an identity morphism, i.e., for every object  $A$  there is a morphism  $1_A \in \text{Hom}_C(A, A)$  such that  $f1_A = f$  for every  $f \in \text{Hom}_C(A, B)$  and  $1_Ag = g$  for every  $g \in \text{Hom}_C(B, A)$ .

Morphisms are also called *arrows*. It is an exercise to see that the identity morphism for each object is unique (by the same argument that the identity of a group is unique). We shall write  $\text{Hom}(A, B)$  for  $\text{Hom}_C(A, B)$  when the category is clear from the context.

The terminology we use throughout the text is common to all categories: a morphism from  $A$  to  $B$  will be denoted by  $f : A \rightarrow B$  or  $A \xrightarrow{f} B$ . The object  $A$  is the *domain* of  $f$  and  $B$  is the *codomain* of  $f$ . A morphism from  $A$  to  $A$  is an endomorphism of  $A$ . A morphism  $f : A \rightarrow B$  is an isomorphism if there is a morphism  $g : B \rightarrow A$  such that  $gf = 1_A$  and  $fg = 1_B$ .

There is a natural notion of a *subcategory* category  $\mathbf{C}$  of  $\mathbf{D}$ , i.e., when every object of  $\mathbf{C}$  is also an object in  $\mathbf{D}$ , and for objects  $A, B$  in  $\mathbf{C}$  we have the containment  $\text{Hom}_{\mathbf{C}}(A, B) \subseteq \text{Hom}_{\mathbf{D}}(A, B)$ .

## Examples

In each of the following examples we leave the details of the verification of the axioms for a category as exercises.

- (1) **Set** is the category of all sets. For any two sets  $A$  and  $B$ ,  $\text{Hom}(A, B)$  is the set of all functions from  $A$  to  $B$ . Composition of morphisms is the familiar composition of functions:  $gf = g \circ f$ . The identity in  $\text{Hom}(A, A)$  is the map  $1_A(a) = a$ , for all  $a \in A$ . This category contains the category of all finite sets as a subcategory.
- (2) **Grp** is the category of all groups, where morphisms are group homomorphisms. Note that the composition of group homomorphisms is again a group homomorphism. A subcategory of **Grp** is **Ab**, the category of all abelian groups. Similarly, **Ring** is the category of all nonzero rings with 1, where morphisms are ring homomorphisms that send 1 to 1. The category **CRing** of all commutative rings with 1 is a subcategory of **Ring**.
- (3) For a fixed ring  $R$ , the category  $R\text{-mod}$  consists of all left  $R$ -modules with morphisms being  $R$ -module homomorphisms.
- (4) **Top** is the category whose objects are topological spaces and morphisms are continuous maps between topological spaces (cf. Section 15.2). Note that the identity (set) map from a space to itself is continuous in every topology, so  $\text{Hom}(A, A)$  always has an identity.
- (5) Let **0** be the empty category, with no objects and no morphisms. Let **1** denote the category with one object,  $A$ , and one morphism:  $\text{Hom}(A, A) = \{1_A\}$ . Let **2** be the category with two objects,  $A_1$  and  $A_2$ , and only one nonidentity morphism:

$\text{Hom}(A_1, A_2) = \{f\}$  and  $\text{Hom}(A_2, A_1) = \emptyset$ . Note that the objects  $A_1$  and  $A_2$  and the morphism  $f$  are “primitives” in the sense that  $A_1$  and  $A_2$  are not defined to be sets and  $f$  is simply an arrow (literally) from  $A_1$  to  $A_2$ ; it is not defined as a set map on the elements of some set. One can continue this way and define  $N$  to be the category with  $N$  objects  $A_1, A_2, \dots, A_N$  with the only nonidentity morphisms being a unique arrow from  $A_i$  to  $A_j$  for every  $j > i$  (so that composition of arrows is uniquely determined).

- (6) If  $G$  is a group, form the category  $\mathbf{G}$  as follows. The only object is  $G$  and  $\text{Hom}(G, G) = G$ ; the composition of two functions  $f$  and  $g$  is the product  $gf$  in the group  $G$ . Note that  $\text{Hom}(G, G)$  has an identity morphism: the identity of the group  $G$ .

**Definition.** Let  $\mathbf{C}$  and  $\mathbf{D}$  be categories.

- (1) We say  $\mathcal{F}$  is a *covariant functor* from  $\mathbf{C}$  to  $\mathbf{D}$  if
- (a) for every object  $A$  in  $\mathbf{C}$ ,  $\mathcal{F}A$  is an object in  $\mathbf{D}$ , and
  - (b) for every  $f \in \text{Hom}_{\mathbf{C}}(A, B)$  we have  $\mathcal{F}(f) \in \text{Hom}_{\mathbf{D}}(\mathcal{F}A, \mathcal{F}B)$ ,
- such that the following axioms are satisfied:
- (i) if  $gf$  is a composition of morphisms in  $\mathbf{C}$ , then  $\mathcal{F}(gf) = \mathcal{F}(g)\mathcal{F}(f)$  in  $\mathbf{D}$ , and
  - (ii)  $\mathcal{F}(1_A) = 1_{\mathcal{F}A}$ .
- (2) We say  $\mathcal{F}$  is a *contravariant functor* from  $\mathbf{C}$  to  $\mathbf{D}$  if the conditions in (1) hold but property (b) and axiom (i) are replaced by:
- (b') for every  $f \in \text{Hom}_{\mathbf{C}}(A, B)$ ,  $\mathcal{F}(f) \in \text{Hom}_{\mathbf{D}}(\mathcal{F}B, \mathcal{F}A)$ ,
  - (i') if  $gf$  is a composition of morphisms in  $\mathbf{C}$ , then  $\mathcal{F}(gf) = \mathcal{F}(f)\mathcal{F}(g)$  in  $\mathbf{D}$
- (i.e., contravariant functors reverse the arrows).

## Examples

In each of these examples the verification of the axioms for a functor are left as exercises. Additional examples of functors appear in the exercises at the end of this section.

- (1) The identity functor  $I_{\mathbf{C}}$  maps any category  $\mathbf{C}$  to itself by sending objects and morphisms to themselves. More generally, if  $\mathbf{C}$  is a subcategory of  $\mathbf{D}$ , the *inclusion functor* maps  $\mathbf{C}$  into  $\mathbf{D}$  by sending objects and morphisms to themselves.
- (2) Let  $\mathcal{F}$  be the functor from  $\mathbf{Grp}$  to  $\mathbf{Set}$  that maps any group  $G$  to the same set  $G$  and any group homomorphism  $\varphi$  to the same set map  $\varphi$ . This functor is called the *forgetful functor* since it “removes” or “forgets” the structure of the groups and the homomorphisms between them. Likewise there are forgetful functors from the categories  $\mathbf{Ab}$ ,  $R\text{-mod}$ ,  $\mathbf{Top}$ , etc., to  $\mathbf{Set}$ .
- (3) The *abelianizing functor* maps  $\mathbf{Grp}$  to  $\mathbf{Ab}$  by sending each group  $G$  to the abelian group  $G^{\text{ab}} = G/G'$ , where  $G'$  is the commutator subgroup of  $G$  (cf. Section 5.4). Each group homomorphism  $\varphi : G \rightarrow H$  is mapped to the induced homomorphism on quotient groups:

$$\bar{\varphi} : G^{\text{ab}} \rightarrow H^{\text{ab}} \quad \text{by} \quad \bar{\varphi}(xG') = \varphi(x)H'.$$

The definition of the commutator subgroup ensures that  $\bar{\varphi}$  is well defined and the axioms for a functor are satisfied.

- (4) Let  $R$  be a ring and let  $D$  be a left  $R$ -module. For each left  $R$ -module  $N$  the set  $\text{Hom}_R(D, N)$  is an abelian group, and is an  $R$ -module if  $R$  is commutative (cf. Proposition 2 in Section 10.2). If  $\varphi : N_1 \rightarrow N_2$  is an  $R$ -module homomorphism, then for every  $f \in \text{Hom}_R(D, N_1)$  we have  $\varphi \circ f \in \text{Hom}_R(D, N_2)$ . Thus

$\varphi' : \text{Hom}_R(D, N_1) \rightarrow \text{Hom}_R(D, N_2)$  by  $\varphi'(f) = \varphi \circ f$ . This shows the map

$$\mathcal{H}\text{om}(D, \_) : N \longrightarrow \text{Hom}_R(D, N)$$

$$\mathcal{H}\text{om}(D, \_) : \varphi \longrightarrow \varphi'$$

is a covariant functor from  $R\text{-Mod}$  to  $\text{Grp}$ . If  $R$  is commutative, it maps  $R\text{-Mod}$  to itself.

- (5) In the notation of the preceding example, we observe that if  $\varphi : N_1 \rightarrow N_2$ , then for every  $g \in \text{Hom}_R(N_2, D)$  we have  $g \circ \varphi \in \text{Hom}_R(N_1, D)$ . Thus  $\varphi' : \text{Hom}_R(N_2, D) \rightarrow \text{Hom}_R(N_1, D)$  by  $\varphi'(g) = g \circ \varphi$ . In this case the map

$$\mathcal{H}\text{om}(\_, D) : N \longrightarrow \text{Hom}_R(N, D)$$

$$\mathcal{H}\text{om}(\_, D) : \varphi \longrightarrow \varphi'$$

defines a *contravariant* functor.

- (6) When  $D$  is a right  $R$ -module the map  $D \otimes_R \_ : N \rightarrow D \otimes_R N$  defines a covariant functor from  $R\text{-Mod}$  to  $\text{Ab}$  (or to  $R\text{-Mod}$  when  $R$  is commutative). Here the morphism  $\varphi : N_1 \rightarrow N_2$  maps to the morphism  $1 \otimes \varphi$ .

Likewise when  $D$  is a left  $R$ -module  $\_ \otimes_R D : N \rightarrow N \otimes_R D$  defines a covariant functor from the category of right  $R$ -modules to  $\text{Ab}$  (or to  $R\text{-Mod}$  when  $R$  is commutative), where the morphism  $\varphi$  maps to the morphism  $\varphi \otimes 1$ .

- (7) Let  $K$  be a field and let  $K\text{-fdVec}$  be the category of all finite dimensional vector spaces over  $K$ , where morphisms in this category are  $K$ -linear transformations. We define the *double dual* functor  $\mathcal{D}^2$  from  $K\text{-fdVec}$  to itself. Recall from Section 11.3 that the dual space,  $V^*$ , of  $V$  is defined as  $V^* = \text{Hom}_K(V, K)$ ; the double dual of  $V$  is  $V^{**} = \text{Hom}_K(V^*, K)$ . Then  $\mathcal{D}^2$  is defined on objects by mapping a vector space  $V$  to its double dual  $V^{**}$ . If  $\varphi : V \rightarrow W$  is a linear transformation of finite dimensional spaces, then

$$\mathcal{D}^2(\varphi) : V^{**} \rightarrow W^{**} \quad \text{by} \quad \mathcal{D}^2(\varphi)(E_v) = E_{\varphi(v)},$$

where  $E_v$  denotes “evaluation at  $v$ ” for each  $v \in V$ . By Theorem 19 in Section 11.3,  $E_v \in V^{**}$ , and each element of  $V^{**}$  is of the form  $E_v$  for a unique  $v \in V$ . Since  $\varphi(v) \in W$  we have  $E_{\varphi(v)} \in W^{**}$ , so  $\mathcal{D}^2(\varphi)$  is well defined.

The functor  $\mathcal{F}$  from  $\mathbf{C}$  to  $\mathbf{D}$  is called *faithful* (or is called *full*) if for every pair of objects  $A$  and  $B$  in  $\mathbf{C}$  the map  $\mathcal{F} : \text{Hom}(A, B) \rightarrow \text{Hom}(\mathcal{F}A, \mathcal{F}B)$  is injective (or surjective, respectively). Thus, for example, the forgetful functor is faithful but not full.

## EXERCISES

- Let  $N$  be a group and let  $\text{Nor-}N$  be the collection of all groups that contain  $N$  as a normal subgroup. A morphism between objects  $A$  and  $B$  is any group homomorphism that maps  $N$  into  $N$ .
  - Prove that  $\text{Nor-}N$  is a category.
  - Show how the projection homomorphism  $G \mapsto G/N$  may be used to define a functor from  $\text{Nor-}N$  to  $\text{Grp}$ .
- Let  $H$  be a group. Define a map  $\mathcal{H}\times$  from  $\text{Grp}$  to itself on objects and morphisms as follows:

$$\mathcal{H}\times : G \rightarrow H \times G, \text{ and}$$

$$\text{if } \varphi : G_1 \rightarrow G_2 \text{ then } \mathcal{H}\times(\varphi) : H \times G_1 \rightarrow H \times G_2 \text{ by } (h, g) \mapsto (h, \varphi(g)).$$

Prove that  $\mathcal{H} \times$  is a functor.

3. Show that the map **Ring** to **Grp** by mapping a ring to its group of units (i.e.,  $R \mapsto R^\times$ ) defines a functor. Show by explicit examples that this functor is neither faithful nor full.
4. Show that for each  $n \geq 1$  the map  $\mathcal{GL}_n : R \rightarrow GL_n(R)$  defines a functor from **CRing** to **Grp**. [Define  $\mathcal{GL}_n$  on morphisms by applying each ring homomorphism to the entries of a matrix.]
5. Supply the details that show the double dual map described in Example 7 satisfies the axioms of a functor.

## 2. NATURAL TRANSFORMATIONS AND UNIVERSALS

As mentioned in the introduction to this appendix, one of the motivations for the inception of category theory was to give a precise definition of the notion of “natural” isomorphism. We now do so, and see how some natural maps mentioned in the text are instances of the categorical concept. We likewise give the categorical definition of “universal arrows” and view some occurrences of universal properties in the text in this light.

**Definition.** Let **C** and **D** be categories and let  $\mathcal{F}, \mathcal{G}$  be covariant functors from **C** to **D**. A *natural transformation* or *morphism of functors* from  $\mathcal{F}$  to  $\mathcal{G}$  is a map  $\eta$  that assigns to each object  $A$  in **C** a morphism  $\eta_A$  in  $\text{Hom}_{\mathbf{D}}(\mathcal{F}A, \mathcal{G}A)$  with the following property: for every pair of objects  $A$  and  $B$  in **C** and every  $f \in \text{Hom}_{\mathbf{C}}(A, B)$  we have  $\mathcal{G}(f)\eta_A = \eta_B\mathcal{F}(f)$ , i.e., the following diagram commutes:

$$\begin{array}{ccc} \mathcal{F}A & \xrightarrow{\eta_A} & \mathcal{G}A \\ \mathcal{F}(f) \downarrow & & \downarrow \mathcal{G}(f) \\ \mathcal{F}B & \xrightarrow{\eta_B} & \mathcal{G}B \end{array}$$

If each  $\eta_A$  is an isomorphism,  $\eta$  is called a *natural isomorphism* of functors.

Consider the special case where  $\mathbf{C} = \mathbf{D}$  and **C** is a subcategory of **Set**, and where  $\mathcal{F}$  is the identity functor. There is a natural transformation  $\eta$  from the identity functor to  $\mathcal{G}$  if whenever  $\mathcal{G}$  maps the object  $A$  to the object  $\mathcal{G}A$  there is a morphism  $\eta_A$  from  $A$  to  $\mathcal{G}A$ , and whenever there is a morphism  $f$  from  $A$  to  $B$  the morphism  $\mathcal{G}(f)$  is compatible with  $f$  as a map from  $\mathcal{G}A$  to  $\mathcal{G}B$ . In fact  $\mathcal{G}(f)$  is uniquely determined by  $f$  as a map from the subset  $\eta_A(A)$  in  $\mathcal{G}A$  to the subset  $\eta_B(B)$  of  $\mathcal{G}B$ . If  $\eta$  is a natural isomorphism, then the value of  $\mathcal{G}$  on every morphism is completely determined by  $\eta$ , namely  $\mathcal{G}(f) = \eta_B f \eta_A^{-1}$ . In this case the functor  $\mathcal{G}$  is entirely specified by  $\eta$ . We shall see that some of the examples of functors in the preceding section arise this way.

### Examples

- (1) For any categories **C** and **D** and any functor  $\mathcal{F}$  from **C** to **D** the identity is a natural isomorphism from  $\mathcal{F}$  to itself:  $\eta_A = 1_{\mathcal{F}A}$  for every object  $A$  in **C**.

- (2) Let  $R$  be a ring and let  $\mathcal{F}$  be any functor from  $R\text{-Mod}$  to itself. The zero map is a natural transformation from  $\mathcal{F}$  to itself:  $\eta_A = 0_A$  for every  $R$ -module  $A$ , where  $0_A$  is the zero map from  $A$  to itself. This is not a natural isomorphism.
- (3) Let  $\mathcal{F}$  be the identity functor from  $\mathbf{Grp}$  to itself, and let  $\mathcal{G}$  be the abelianizing functor (Example 3) considered here as a map from  $\mathbf{Grp}$  to itself. For each group  $G$  let  $\eta_G : G \rightarrow G/G'$  be the usual projection map onto the quotient group. Then  $\eta$  is a natural transformation (but not an isomorphism) with respect to these two functors. (We call the maps  $\eta_G$  the *natural projection* maps.)
- (4) Let  $\mathcal{G} = D^2$  be the double dual functor from the category of finite dimensional vector spaces over a field  $K$  to itself (Example 7). Then there is a natural isomorphism  $\eta$  from the identity functor to  $\mathcal{G}$  given by

$$\eta_V : V \rightarrow V^{**} \quad \text{by} \quad \eta_V(v) = E_v$$

where  $E_v$  is “evaluation at  $v$ ” for every  $v \in V$ .

- (5) Let  $\mathcal{GL}_n$  be the functor from  $\mathbf{CRing}$  to  $\mathbf{Grp}$  defined as follows. Each object (commutative ring)  $R$  is mapped by  $\mathcal{GL}_n$  to the group  $GL_n(R)$  of  $n \times n$  invertible matrices with entries from  $R$ . For each ring homomorphism  $f : R \rightarrow S$  let  $\mathcal{GL}_n(f)$  be the map of matrices that applies  $f$  to each matrix entry. Since  $f$  sends 1 to 1 it follows that  $\mathcal{GL}_n(f)$  sends invertible matrices to invertible matrices (cf. Exercise 4 in Section 1). Let  $\mathcal{G}$  be the functor from  $\mathbf{CRing}$  to  $\mathbf{Grp}$  that maps each ring  $R$  to its group of units  $R^\times$ , and each ring homomorphism  $f$  to its restriction to the groups of units (also denoted by  $f$ ). The *determinant* is a natural transformation from  $\mathcal{GL}_n$  to  $\mathcal{G}$  because the determinant is defined by the same polynomial for all rings so that the following diagram commutes:

$$\begin{array}{ccc} GL_n(R) & \xrightarrow{\det} & R^\times \\ \mathcal{GL}_n(f) \downarrow & & \downarrow f \\ GL_n(S) & \xrightarrow{\det} & S^\times \end{array}$$

Let  $\mathbf{C}$ ,  $\mathbf{D}$  and  $\mathbf{E}$  be categories, let  $\mathcal{F}$  be a functor from  $\mathbf{C}$  to  $\mathbf{D}$ , and let  $\mathcal{G}$  be a functor from  $\mathbf{D}$  to  $\mathbf{E}$ . There is an obvious notion of the composition of functors  $\mathcal{GF}$  from  $\mathbf{C}$  to  $\mathbf{E}$ . When  $\mathbf{E} = \mathbf{C}$  the composition  $\mathcal{GF}$  maps  $\mathbf{C}$  to itself and  $\mathcal{FG}$  maps  $\mathbf{D}$  to itself. We say  $\mathbf{C}$  and  $\mathbf{D}$  are *isomorphic* if for some  $\mathcal{F}$  and  $\mathcal{G}$  we have  $\mathcal{GF}$  is the identity functor  $\mathcal{I}_{\mathbf{C}}$ , and  $\mathcal{FG} = \mathcal{I}_{\mathbf{D}}$ . By the discussion in Section 10.1 the categories  $\mathbb{Z}\text{-Mod}$  and  $\mathbf{Ab}$  are isomorphic. It also follows from observations in Section 10.1 that the categories of elementary abelian  $p$ -groups and vector spaces over  $\mathbb{F}_p$  are isomorphic. In practice we tend to identify such isomorphic categories. The following generalization of isomorphism between categories gives a broader and more useful notion of when two categories are “similar.”

**Definition.** Categories  $\mathbf{C}$  and  $\mathbf{D}$  are said to be *equivalent* if there are functors  $\mathcal{F}$  from  $\mathbf{C}$  to  $\mathbf{D}$  and  $\mathcal{G}$  from  $\mathbf{D}$  to  $\mathbf{C}$  such that the functor  $\mathcal{GF}$  is naturally isomorphic to  $\mathcal{I}_{\mathbf{C}}$  (the identity functor of  $\mathbf{C}$ ) and  $\mathcal{FG}$  is naturally isomorphic to the identity functor  $\mathcal{I}_{\mathbf{D}}$ .

It is an exercise that equivalence of categories is reflexive, symmetric and transitive. The example of Affine  $k$ -algebras in Section 15.5 is an equivalence of categories (where one needs to modify the direction of the arrows in the definition of a natural

transformation to accommodate the contravariant functors in this example). Another example (which requires some proving) is that for  $R$  a commutative ring with 1 the categories of left modules  $R\text{-Mod}$  and  $M_{n \times n}(R)\text{-Mod}$  are equivalent.

Finally, we introduce the concepts of universal arrows and universal objects.

### Definition.

- (1) Let  $\mathbf{C}$  and  $\mathbf{D}$  be categories, let  $\mathcal{F}$  be a functor from  $\mathbf{C}$  to  $\mathbf{D}$ , and let  $X$  be an object in  $\mathbf{D}$ . A *universal arrow* from  $X$  to  $\mathcal{F}$  is a pair  $(U(X), \iota)$ , where  $U(X)$  is an object in  $\mathbf{C}$  and  $\iota : X \rightarrow \mathcal{F}U(X)$  is a morphism in  $\mathbf{D}$  satisfying the following property: for any object  $A$  in  $\mathbf{C}$  if  $\varphi$  is any morphism from  $X$  to  $\mathcal{F}A$  in  $\mathbf{D}$ , then there exists a unique morphism  $\Phi : U(X) \rightarrow A$  in  $\mathbf{C}$  such that  $\mathcal{F}(\Phi)\iota = \varphi$ , i.e., the following diagram commutes:

$$\begin{array}{ccc} X & \xrightarrow{\iota} & \mathcal{F}U(X) \\ & \searrow \varphi & \downarrow \mathcal{F}(\Phi) \\ & & \mathcal{F}A \end{array}$$

- (2) Let  $\mathbf{C}$  be a category and let  $\mathcal{F}$  be a functor from  $\mathbf{C}$  to the category  $\mathbf{Set}$  of all sets. A *universal element* of the functor  $\mathcal{F}$  is a pair  $(U, \iota)$ , where  $U$  is an object in  $\mathbf{C}$  and  $\iota$  is an element of the set  $\mathcal{F}U$  satisfying the following property: for any object  $A$  in  $\mathbf{C}$  and any element  $g$  in the set  $\mathcal{F}A$  there is a unique morphism  $\varphi : U \rightarrow A$  in  $\mathbf{C}$  such that  $\mathcal{F}(\varphi)(\iota) = g$ .

### Examples

- (1) (*Universal Arrow: Free Objects*) Let  $R$  be a ring with 1. We translate into the language of universal arrows the statement that if  $U(X)$  is the free  $R$ -module on a set  $X$  then any set map from  $X$  to an  $R$ -module  $A$  extends uniquely by  $R$ -linearity to an  $R$ -module homomorphism from  $U(X)$  to  $A$  (cf. Theorem 6, Section 10.3): Let  $\mathcal{F}$  be the forgetful functor from  $R\text{-Mod}$  to  $\mathbf{Set}$ , so that  $\mathcal{F}$  maps an  $R$ -module  $A$  to the set  $A$ , i.e.,  $A = \mathcal{F}A$  as sets. Let  $X$  be any set (i.e., an object in  $\mathbf{Set}$ ), let  $U(X)$  be the free  $R$ -module with basis  $X$ , and let  $\iota : X \rightarrow \mathcal{F}U(X)$  be the set map which sends each  $b \in X$  to the basis element  $b$  in  $U(X)$ . Then the universal property of free  $R$ -modules is precisely the result that  $(U(X), \iota)$  is a universal arrow from  $X$  to the forgetful functor  $\mathcal{F}$ .

Similarly, free groups, vector spaces (which are free modules over a field), polynomial algebras (which are free  $R$ -algebras) and the like are all instances of universal arrows.

- (2) (*Universal Arrow: Fields of Fractions*) Let  $\mathcal{F}$  be the forgetful functor from the category of fields to the category of integral domains, where the morphisms in both categories are *injective* ring homomorphisms. For any integral domain  $X$  let  $U(X)$  be its field of fractions and let  $\iota$  be the inclusion of  $X$  into  $U(X)$ . Then  $(U(X), \iota)$  is a universal arrow from  $X$  to the functor  $\mathcal{F}$  (cf. Theorem 15(2) in Section 7.5).
- (3) (*Universal Object: Tensor Products*) This example refers to the construction of the tensor product of two modules in Section 10.4. Let  $\mathbf{C} = R\text{-Mod}$  be the category of  $R$ -modules over the commutative ring  $R$ , and let  $M$  and  $N$  be  $R$ -modules. For each  $R$ -module  $A$  let  $\text{Bilin}(M, N; A)$  denote the set of all  $R$ -bilinear functions from  $M \times N$  to  $A$ . Define a functor from  $R\text{-Mod}$  to  $\mathbf{Set}$  on objects by

$$\mathcal{F} : A \longrightarrow \text{Bilin}(M, N; A),$$

and if  $\varphi : A \rightarrow B$  is an  $R$ -module homomorphism then

$$\mathcal{F}(\varphi)(h) = \varphi \circ h \quad \text{for every } h \in \text{Bilin}(M, N; A).$$

Let  $U = M \otimes_R N$  and let  $\iota$  be the bilinear function

$$\iota : M \times N \rightarrow M \otimes_R N \quad \text{by} \quad \iota(m, n) = m \otimes n,$$

so  $\iota$  is an element of the set  $\text{Bilin}(M, N; M \otimes_R N) = \mathcal{F}U$ . Then  $(M \otimes_R N, \iota)$  is a universal element of  $\mathcal{F}$  because for any  $R$ -module  $A$  and for any bilinear map  $g : M \times N \rightarrow A$  (i.e., any element of  $\mathcal{F}A$ ) there is a unique  $R$ -module homomorphism  $\varphi : M \otimes_R N \rightarrow A$  such that  $g = \varphi \circ \iota = \mathcal{F}(\varphi)(\iota)$ .

## EXERCISES

1. Let  $\text{Nor}-N$  be the category described in Exercise 1 of Section 1, and let  $\mathcal{F}$  be the inclusion functor from  $\text{Nor}-N$  into  $\text{Grp}$ . Describe a functor  $\mathcal{G}$  from  $\text{Nor}-N$  into  $\text{Grp}$  such that the transformation  $\eta$  defined by  $\eta_G : G \rightarrow G/N$  is a natural transformation from  $\mathcal{F}$  to  $\mathcal{G}$ .
2. Let  $H$  and  $K$  be groups and let  $\mathcal{H}\times$  and  $\mathcal{K}\times$  be functors from  $\text{Grp}$  to itself described in Exercise 2 of Section 1. Let  $\varphi : H \rightarrow K$  be a group homomorphism.
  - (a) Show that the maps  $\eta_A : H \times A \rightarrow K \times A$  by  $\eta_A(h, a) = (\varphi(h), a)$  determine a natural transformation  $\eta$  from  $\mathcal{H}\times$  to  $\mathcal{K}\times$ .
  - (b) Show that the transformation  $\eta$  is a natural isomorphism if and only if  $\varphi$  is a group isomorphism.
3. Express the universal property of the commutator quotient group — described in Proposition 7(5) of Section 5.4 — as a universal arrow for some functor  $\mathcal{F}$ .
